A SECOND CENTURY OF FERNS.
A SECOND

CENTURY OF FERNS;

BRING

FIGURES WITH BRIEF DESCRIPTIONS

OF

One Hundred

NEW, OR RARE, OR IMPERFEKTLY KNOWN SPECIES OF

FERNS;

FROM VARIOUS PARTS OF THE WORLD;

BY

SIR WILLIAM JACKSON HOOKER, K.H.,

DIRECTOR OF THE ROYAL BOTANICAL GARDENS, KEW.

LONDON.

WILLIAM PAMPLIN 45, FRITH STREET, SOHO SQUARE.

MDCCCLXI.
TO

DR. GEORGE METTENIUS,

PROFESSOR OF BOTANY, AND DIRECTOR OF THE BOTANIC GARDEN

AT THE UNIVERSITY OF LEIPZIG,

THE ABLE AUTHOR OF

"FILICES HORTI BOTANICI LIPSIENSIS,"

AND OF VARIOUS MEMOIRS,

"UBER EINIGE PARRNGATTUNGEN,"

THIS CENTURY OF FERNS

IS DEDICATED,

IN TESTIMONY OF GREAT RESPECT AND ESTEEM, BY

THE AUTHOR.

Royal Gardens, Kew,
May, 1861.
PREFATORY NOTICE.

Of all the Families of plants, perhaps there is none that needs so much to be illustrated by figures as the Ferns. They are, from their variability of character, and owing to the different forms they exhibit in different individuals of the same species, and even in different parts of the same individual, especially in the very compound kinds, exceedingly difficult of verbal definition, and hence the descriptions of writers have been so greatly misunderstood, even those that have been the most full and most accurately worded.

It was the want of such Fern-figures, as helps to a more thorough knowledge of these lovely plants, that induced us to devote the whole of the last volume (the Tenth) of our "Ieones Plantarum," exclusively, to this Family, and we think Mr. Pamplin did right in issuing copies of this volume separate, to those who might not care to possess the entire work, and under the title of a "Century of Ferns." So favourably was this volume received that it has induced the Author to publish another and "Second Century," the volume now before us.

There is indeed no scarcity of materials for many such volumes, could sufficient patronage be insured; for the discovery of new species has of late years been quite extraordinary, in different parts of the world; and it would be still more extraordinary if we could persuade ourselves
that all that go by the name of new discoveries, were really so. If we take Mr. Moore's useful and laborious "Index Filicum" as a test of the numerical statistics of Ferns, the number appears great indeed. The eleventh part of this "Index" has recently been issued, bringing the Catalogue down to the letter C, and to the end of the genus *Cuspidaria.* Thus the work at present only embraces the Genera (alphabetically arranged) of the first three letters of the alphabet (A—C). These include 47 Genera and 1069 species! The total of such genera to be recorded are 186, of which about one-eighth only have been elaborated, so that if we consider the remaining seven-eighths of the genera to possess the same proportional amount of species, which may possibly be the case, this brings us to 8000 different kinds of Ferns described in books by persons worthy of credit from their name and character; to say nothing of the multitudes of synonyms, which are legion.

But it must be recollected that Mr. Moore necessarily reckons, as *species* of authors, a great number which he has no means of verifying, nor of judging whether they ought, or ought not to be rejected, as he has done in the case of many others:—and of which there is too much reason to fear that a large proportion would come into the latter category. If we reckon the number of well-ascertained Ferns at half the amount enumerated in the "Index Filicum," viz. at 4000 species, it will perhaps nearly accord with the truth.

Nothing will so much tend to a correct knowledge of these as accurate figures, published on a cheap scale, as are the two "Centurics" now under consideration:—and we have had
the privilege of bringing into notice many novelties of great interest derived from the researches of our friends and correspondents in different quarters of the globe, from some countries of which, till now, the vegetable productions were comparatively unknown to the man of science. We allude particularly to the Fiji Islands, to Japan and China, to Borneo, Tropical Africa, East and West, &c. &c.; the results of the labours of Brackenridge, Milne, Maegillivray, Harvey, Seemann (Fiji); Wright, Wilford, Urquhart, Alcock, Hodgson (China and Japan); Low, Motley, Lobb (Borneo); Vogel, Balkie and Barter, Kirk, in Livingstone’s Expedition (Tropical Africa), and others too numerous to mention, but whose names stand recorded in these pages. Not a few we trust will be found faithfully and unmistakeably exhibited in our two Centuries; and many, for which we have no space here, will be received, and if possible figured in our “Species Filicum,*” now in course of Publication.

ROYAL GARDENS, KEW,

MAY, 1861.

* "Species Filicum; being descriptions of the known Ferns, particularly of such as exist in the Author’s Herbarium, or are, with sufficient accuracy, described in works to which he has had access; accompanied with numerous figures, by Sir W. J. Hooker.” Of this work three volumes have appeared, with 210 plates. Vol. IV. is now in the press.

TAB. 1.

Trichomanes Henzaianum, Parish.

Caudice filiformi repente ramoso parce nigro-tomentoso, frondibus parvis remotiusculis brevi-stipitatis obovato-subflabelliformibus membranaceis subnitidis vix semiluneliam longis marginibus magis minusve irregulariter lobatis vix pinnatifidis lobis brevibus obtusis, venis apice libris primaris paucis subflabellato-pinnatis satis distinctis, secundaris iis parallelis arctis deliculatis venulis transversis junetis et ita frondibus minute remotiusculis brevibus obvato-subflabelliformibus, limbo dilatato integro, stipite gracili vix lineam longo.

Trichomanes Henzaianum, Parish in litt.

HAB. Detected by Mr. Henzaiz, and the Rev. C. S. P. Parish, partially clothing the trunks of trees at Moulmein, 1859.

Dr. Van Den Bosch, of Leyden, distinguished by his writings and admirable figures of Mosses, is now happily engaged on a monograph, with numerous figures on the beautiful family, among Ferns, of Hymenophyllaceae. He has already given to the world a valuable "Synopsis" of the group, with full descriptions of new or critical species. Our present individual, will rank near to Tr. sublimbatum of Mueller, to which Van Den Bosch refers, and probably quite correctly, my Java form of Tr. musceoides, (Sp. Fil. i. p. 117). From that, however, our plant may be known by its much smaller size, and different form, greener color, more delicate texture; but, above all, by the involucre, of which the limb in T. sublimbatum extends to the margin of the frond, while in our plant, the lobe of the frond extends much beyond the involucre; and has, indeed, the appearance of half an involucre attached to the frond, as occurs in not a few davalliacous plants.

Fig. 1. Plants, nat. size, (from a drawing by Mr. Parish). f. 2, 3. Portions of plants slightly magnified. f. 4. Single fertile frond. f. 5. Two involucres, one laid open showing the sorus. f. 6. Portion of the frond, to show the cellular structure. f. 7. Receptacle and capsules. f. 8. Capsule; more highly magnified.

Cest. 2, vi. 1.
WOODSIA (HYMENOCYSTIS) POLYSTICHOIDES, Eaton.

Spithaemæa ad pedalem dense cæspitosa, caudice subnullo, frondibus subcoriaceo-membranaeis opacis lanceolatis pin- natis, pinnis patentibus numerosis approximatis sessilibus . 6-7 lineas longis lanceolatis obtusis basi enneato-truncatis sursum acute auriculatibus junioribus sparsum palæaceis villosis que demum glabris margine integerrimis vel apicem versus obsoletissime crenatis, costa indistincta, venis immor- cis simplicibus vel furcatis libris ad marginem apice soriferis, involucro et squamis 4-5 tenui-membranaeis in orbem dispositis imbricatis longe ciliatis, stipitis castaneis rachique straminea nitidissimis deciduo paleaceis.

HAB. Hakodadi, Japan, C. Wright.

A very remarkable and very pretty Fern, for which I am indebted to Mr. Wright and Mr. Eaton, who observe (in litt.) that this ought, perhaps, to be made the type of a new genus; for that “the parts of the indusium imbricate over each other.” It is however, I think, very difficult, where the indusium (or involucre) is of so very delicate and fragile a nature, to say whether it is of the structure now mentioned, or whether, being first entire, it may not afterwards burst from the top into a few unequal valves, which may appear to be imbricated, and as is the case in the group or subgenus Physematium, Klfs. (Hymenocystis, C. A. Meyer), to which Mr. Eaton has, as it appears to me, properly referred it.

Fig. 1. Fertile pinna, seen from beneath. ʃ. 2. Portion of the same. ʃ. 3. Involucre partially closed. ʃ. 4. In- volucre open, and showing the sorus. ʃ. 5. Portion of a valve of the involucre. ʃ. 6. Capsule:—magnified.

COTT. 2. T. 2.
Asplenium (Euassplenium) Lugubre, Hook.

Glabrum, colore toto nigricante, caudice repente crassiusculo radiculose, frondibus caespitosis brevistipitatis spithamaeis ad pedalem lato-lanceolatis inferne attenuatis pinnatis apicem versus pinnatifidis, pinnis sessilibus horizontaliter patentibus segmentisque lanceolato-falcatis vix acuminatis inaequaliter subduplicato-serratis membranaceis rigidis subopacis, venis simplicibus v. furcatis apicibus intra marginem clavatis, soris versus apicem pinnarum vel segmentorum, involucris angustis nigris, stipitibus rachibusque villis paleaceis aterrimis patentibus crinitis.

Hab. Kina Ballu, Borneo, Hugh Low, junr. Esq.

A very peculiar looking Asplenium, entirely of a black colour in its dried state, having the short stipes and rachis clothed with patent, long-spreading, intensely black, paleaceous flexuose hairs, or scales. The appearance of the entire plant is that of having grown in water, and the pinnae and segments are more or less erose, and jagged at the margin, and the substance is formed of closely compacted cells, in the younger and subpellucid specimens exhibiting a minutely reticulated appearance, when held between the eye and the light.

Fig. 1. Portion of a pinna to show the venation. f. 2. Portion of a fertile pinna. f. 3. Scale from the rachis:—magnified.

Cent. 2. p. 3.
Struthiopteris orientalis, Hook.

Elata, frondibus ovatis ovato-oblongisve pinnatis, pinnis sterilibus pinnatifidis submembranecis lacinis ovatis obtusis, fertilibus lato-linearibus coriaceis planis, involucris arcte appressis dorsum totum tegentibus intisis nitidissimis integerrimis, demum affine patentissimis erosis, stipite raebi costisque interne deciduo-paleaceis.

A single glance at the fertile pinnae of this fine species, is sufficient to assure any one of its distinctness from S. Germanica, of Willdenow (Pensylvanica of the U. States Botanists); not only are they much longer and broader and flatter, (less cylindrical) and never moniliform; but the involucre is of a very different nature, so broad as completely to cover the back of the pinnules, the entire edges meeting at the back, and never breaking up into uniform segments; and the texture is thin and membranaceous, but firm, very glossy, and of a very dark chestnut colour, suddenly conuplicate, and pressed close to the sori on the back; whereas in S. Germanica, the moniliform fertile pinnae have the involucre rolled back as it were, so as to cover the sori, and of the same texture and color as the pinna itself. The sterile frond too, which is much attenuated at the base, is here abrupt. As a species, it may probably be found to have as extensive a range in the Eastern, as S. Germanica has in the Western world, (including Europe in this region), for it has already been found in Sikkim Himalaya. I detected one specimen in a collection of Assam Ferns; and it appears again in the Northern Island of Japan, Hakodadi.

Fig. 1. Small fertile pinna. f. 2. Portion of a fertile pinna; magnified. f. 3. Portion of a sterile frond; nat. size. f. 5. Portion of a sterile pinna, showing the venation; magnified.

Cest. 2. r. 4.
Caudice crassiusculo repente, frondibus vix stipitatis digitalibus firmis rigidis dense cespitosis lineari-lanceolatis pin-natis, pinnis remotis patentibus apice pilifcris, sterilibus angustissime linearibus, fertilibus spatulatis acutis margine superiore reflexo, vena (seu costa) solitaria infra apicem terminante clavata sorifera, soris solitariis oblongis apicem dilatatum pinnae occupantibus, rachi angusta lineari-subalata patentim villosa.

HAB. Kina Ballu, Borneo, Hugh Low, Junr. Esq.

As far as I can judge from Fée’s figure and description of his Plectopteris gracilis, it is identical with the Calymmodon cucullata of Presl, and the Grammitis cucullata of Blume, and of J. Smith; and no less so with Grammitis denticulata of Blume, (Polypodium cucullatum of Nees and Blume in Nov. Act. Acad. Nat. Cur., and P. denticulatum of Bl. Syn. Fil. Jav.) If this be correct, this genus (or section of Polypodium or Grammitis, according to the views of Botanists,) is reduced to a solitary species; but to this I have added the very elegant Fern now before us, which I prefer retaining in Grammitis. It is readily distinguished by the more slender habit, and deeply and narrowly divided frond, rather pinnate (with the rachis narrow-winged) than pinnatifid; the sterile pinnae are narrow linear almost acicular, while the fertile ones are truly spatulate or claviform, and mostly confined to the middle or upper part of the frond.

I may observe that the Grammitis cucullata, of an unusually large size, is also found on Kina Ballu, by Mr. Hugh Low, Junr.

Fig. 1. Portion of a fertile frond, seen from beneath.  f. 2. Single fertile pinna.  f. 3. Capsule:—magnified.
Polypodium Andinum, Hook.

Caudice brevi repente, frondibus membranaceis cespitosis. digitalibus ad semipedalem oblongo-linearibus vix acuminatis ad basin attenuatis fulvo-villosis ciliatisque ad raariginem solummodo pinnatifidis, lobis brevibus obtusis, costa tenui, venis furcatis intra marginem desinentibus, venula superiore perbrevi apice soriferis, soris globosis subellipticosae prope costam utrinque uniserialibus singulo lobo oppositis.

Hab. Andes of Quito, on the banks of the river Hondacha, Jameson, n. 780. On Mount Picóte, near Moyobambu; Peru, C. W. Nilson (in Spruce’s Plants of Peru, n. 4780).

A very pretty and very peculiar species of the extensive Genus Polypodium, of which I do not find any description, and which seems confined to the Andes of Ecuador and Peru; at least, I have seen it from no other quarter. It is remarkable in the almost ligulate form of the small thin and membranaceous fronds, cut at the margin, with great regularity, into very short and obtuse lobes; the whole, on both surfaces, and at the margin, clothed with long, but rather sparse fulvous hairs. The color is pale green; in the older specimens stained with yellow and brown. The fronds seem destitute of stipes, and are decurrent to their very base, where the costa is often blackish. It may rank near the West Indian P. Serricula of Fée, but that has much narrower fronds, deeply pinnatifid, the lobes 1-veined, and the sorus placed within the lobe.

Fig. 1. Portion of the sterile frond, showing the venation. f. 2. Portion of a fertile frond: magnified.
TAB. VII.

GRAMMITIS CORDATA, SW. — VAR. SUBBIPINNATA.

Caudice brevi crasso copioso radiculoso superne palaeaceo, stipitibus caepitosis 1-2-uncialibus radique deciduo squamosis intense nigro-ebeneis nitidissimis, frondibus erectis flexuosis curvatisve subcoriaceis 3-4-uncialibus ad spithamesam supra viridibus nudis subtus dense imbricatis ferruginco-palaeaceis pinnatis, squamis ovato-lanceolatis magis minusve longis acuminatis subellipto-dentatis subintegerrimisque, pinnis semuniuian ad 1½ uncinum longis remotiusculus sessilis pinnato-oblongis oblongisve horizontabiliter patentibus integris lobato-pinnatifidis magis minusve profundis non raro iterum pinnatis rarius subauriculatis, venis liberis pinnatis apice clavatis, soris oblongis.

 Kunze, and following him, all succeeding authors have pronounced that the admirable figure of Gymnogramme "cordata," of Dr. Greville in Lc. Fil., is not the Grammitis cordata of Swartz; but they refer it to the G. Capensis of Sprague. We maintain, that it perfectly accords with all the essential characters and full descriptions of the illustrious Swede: but it will accord with what Kunze figures and describes as the G. Capensis; nevertheless, we are quite willing to declare our opinion that the two are varieties of each other, for we can trace them through their several stages in our Herbarium, in the following forms or varieties. 1. Pinnata; pinnis oblongis subintegerrimis. Ceterach Capensis, Kze. in Analog Pfl. p. 13. t. 8. Fée, Gen. Fil. Tab. 30. f. 4. (one pinnula slightly pinnatifid.) 2. Pinnato-pinnatifida; pinnis cordatis profunde pinnatifidis. Grammitis cordata, Sw. i. e. and Gymnogramme cordata, Hook. et Grev. l. c. 3. Subbipinnata; pinnis angusto-oblongis profunde pinnatifidis pinnatifidisque. Gymnogramme Capensis, Spr. in Zeyp. Pl. Cap. (Herb. Nostr.) Kze. in Linnaea, 6. p. 183. Ceterach Capensis, Fée, Gen. Fil. Tab. 30. f. 3. (et Tab. Nostr. VII). I may add, a 4th state, or a subvariety of the latter. 4. Nudinclusa: frondibus parce palaeaceis, squamis minoribus subintegerrimis. GymnogrammeNamaquensis, Popp and Rawson, Syn. Fil. Afr. Austr. p. 42. This is found both at the Cape, and in St. Helena.

Fig. 1. Scale of the frond. f. 2. Pinnule. f. 3. Pinnule showing the venation, and two sori: — magnified.
Gymnogramme pumila, Spreng

Caudice repente filiformi parce fibroso, frondibus fasciculatis
\[\frac{1}{2}\text{-biuncias longis ad basin setaceo-paleaceis sessilibus}
\text{submembranaceis flabelliformi-cuneatis basi longe attenuatis}
\text{superne palmatim irregulariter subdichotome incisis, segmentis}
\text{aeutinseulis integerrimis, venis flabellato-dichotomis (costa nulla)}
\text{liberis ante apicem evaneseentibus, soris linearibus elongatis}
\text{non raro (eum venis) dichotomis demum magis minusve confluentibus.}

A very distinct and remarkable Fern; till recently, supposed to be peculiar to French and Dutch Guiana, now found in Brazil, and, still more recently even, off the Coast of Veraguas in the Pacific.

Fig. 1. Fertile frond. f. 2. Sterile frond. f. 3. Portion of a fertile frond, with sori partially removed from the receptacle:—magnified.
Gymnogramme reniformis, Mart.

Caudice brevi eraso basi fibroso superne copiose paleaceo, squamis subulatis ferrugineis nitidis, stipitibus caespitosis 3-uncialiibus ad semipedalem ebeneis, frondibus sesquiuncialibus coriaceis reniformi-rotundatis, venis approximate dichotomis, soris linearibus parallelis in zonam semilunatum discum occupantem confluentibus.

Hab. Brazil; dense woods on Mount Cupati, near the River Japura, Martius. Near Tarapota, Eastern Peru, on Mount Guayrapurima, Spruce, 1856.

One of the rarest and most beautiful of Ferns, with its undivided reniform fronds, and the curious crescent-shaped mass of sori, and the glossy eburneous stipites. I am not aware that it has ever been gathered, but by the two eminent Botanists and S. American travellers just mentioned. Mr. Moore, in adopting the Genus Pterozonium, does not fail to remark, that it is "technically not very different from Gymnogramme, but the aspect of the plant is so peculiar, that the parallel contiguous receptacles, from which result a broad submarginal confluent sorus, may well be considered sufficiently distinctive." I am not aware that its habit is more peculiar in the genus than the Gymnogramme figured in our preceding plate, which, nevertheless, Mr. Moore properly retains in that genus, rather than adopt J. Smith and Fée's Hecistopteris. At any rate, our present Fern is not more remarkable among the species of Gymnogramme, than Adiantum reniforme and asarifolium and Parishii, Trichomanes reniforme, and Lindseya reniformis, are in their respective genera.

Martius appears to have gathered specimens nearly a foot tall.

Fig. 1. One half of a fertile frond, seen from beneath. f: 2. Portion of do., showing the arrangement of the sori on the veins, and the receptacles:—magnified.
Polypodium (Eupolypodium) Sprucei, Hook.

Nanum, caudice brevi subfiliformi repente, stipitibus dense cespitosi vix bilinearisibus, frondibus membranacisis subunciam longis oblongo-subspathulatis obtusis indivisis integerrimis utrinque marginibus stipitibusque villis longis ferrugineis basi latioribus scariosis pilosis, costa gracili flexuosa, venis obliquis remotis simplicibus spicce clavatis intra marginem terminantibus, soris paucis in apicem venarum superiorum globosis.

Hab. Near Tarapota, Eastern Peru, Spruce, n. 4746.

I do not find, anywhere described, a species which will agree with this; notwithstanding, the valuable "Enumeratio Specierum" of the Genus Polypodium, lately published by Mettenius, in which he enumerates 268 species: but, in so doing he considers Polypodium in its more extended, or I may say, Willdenovian sense; omitting, however, Phegopteris, of which, he has a separate "Enumeratio," of no less importance.

Fig. 1. Back and front view of a frond; magnified. f. 2. Apex of a fertile frond:—more magnified.
Asplenium (Eurasplenum) trilobum, Cav.

Parvum, caudice erassiusculo erecto ad apicem paleaceo, squamis imbricatis nitidis, stipitibus caespitosis 2-2½ pollices longis, frondibus coriaceis rhombis acuminatis integris crenatis vel 3-lobis segmentis acuminatis magis minusve incisis lobo intermedio longiore, venis immersis pluribus subflabellatim dichotomis, soris majuseulis erecto-patentibus lineari-oblongis, involucris rigidis fuscis.

Asplenium parvulum (small state), Hook. Ic., Pl. t. 222.

A species easily recognized by its size and trapezoid form. A. trapezoides, indeed, is a more appropriate name than A. trilobum; but the latter has the right of priority. Our Aspl. parvulum of the Icones Plantarum, is merely a smaller and young state of this; we were the more disposed to think it distinct, from its being detected on the Atlantic side of America: having been previously known only on the Pacific coasts.

Fig. 1. Portion of a frond:—magnified.
Polypodium (Eupolypodium) trichosorum, Hook.

Caudice subrepente crassiusculo fulvo-crinito, stipitibus cæspitosis 2-3-uncialibus gracilibus filiformibus, frondibus indi-visis 4-5-uncialibus subspathulato-lanceolatis membranaceis translucidis flavo-viridibus obtusiusculis integerrimis vel crenato-lobulatis (lobis obtusis) supra parce subitus marginibus stipitique pilis ferrugineis patentibus longis copiose crinitis, venis patentibus flexuosis subdichotome pinnatis, venulis apice clavatis, soris sub-4-serialibus parvis in apicem venularum, pilis plurimis inter capsulas.

Hab. On Trees, forest of Archedona, Quitinian Andes, Prof. W. Jameson, n. 349.

This is one among the many Andinian Ferns, which, as far as my researches extend, I take to be new, and for which I am indebted to Prof. W. Jameson’s zeal and kindness. It is a graceful Fern, probably pendent in its native locality, judging from the slenderess of the stipes and a peculiar curvature in many of the specimens at the setting on of the frond upon the stipes.

Fig. 1. Portion of the upper side of a frond. f. 2. 3 portions of the underside with sori:—magnified.
Hymenophyllum Simonsianum, Hook.

Caudice filiformi gracili longe repente, frondibus solitariis distantibus oblongo-lanceolatis membranaceis laxis fuscis bipinnatifidis in stipitem brevem gracilem basi attenuatis apice obtusis, lobis primariis semiuncialibus oblique cuneatis sub lente argute serratis margine inferiore truncatis integris superiore cum apice lobato-pinnatifidis, lobulis paucis (3-5) obtusissimis, involucris in lobis terminalibus frondis ovalibus subovatisque exsertis profunde bivalvibus, valvis convexis subspinuloso-serratis, venis apice clavatis, soris inclusis recaptaeum tegentibus.

Hab. Khasya Hills, Eastern Bengal, Simons.

This does not appear to be anywhere described, though it must be confessed, that in so extensive a natural genus, it is very difficult, and in a few words, to define the character of any particular kind. Accurate figures are most to be depended upon.

Fig. 1. A superior fertile lobe. f. 2. Involucre laid open vertically shewing the sorus. f. 3. Entire involucre:—magnified.
Xiphopteris Jamesoni, Hook.

That the species of the Genus Xiphopteris are very variable, is notorious to every student of Ferns; and, I believe that the X. myosuroides and X. serrulata are now generally looked upon as forms of one species. It may, therefore, be considered a bold step to constitute a species of the present singular and particularly neatly formed kind, which, at first sight, and independent of its fertile caada, has more the appearance of some neckeroid moss, or some delicately pinnated Jungermannia, than a Fern. Instead of being only strongly "toothed" as is characteristic of Xiphopteris generally, it is so deeply pinnatified, nearly to the rachis, that it might almost be called pinnate: and in an advanced state of the plant, these segments or pinnae, fall off partially or entirely, leaving the rachis like a long, stout, naked bristle.

Mr. Moore, whose views always deserve attention, observes, that to him the sori of the genus appear to be produced in a line contiguous to the mid-rib, and seem little different from Pleurogramme. To me, they appear to be decidedly on the lateral thickened veins, extending from the costa to the apex, just within the margin: so difficult is it for all to see with the same eyes, and so much is there yet to learn, in the structure of the fructification of Ferns.

Fig. 1. Upper portion of a fertile frond. f. 2. Segments, superior side. f. 3. Portion of a frond, inferior side. f. 4. Portion of a segment of a frond with one sorus, and the receptacle of a sorus. f. 5. Capsule:—magnified.
Deciduo pubescenti subrepente fibroso, stipitibus cespitosis erectis longitudine variantibus, frondibus pedalibus bipedalibus et ultra subheoreaiiis glabris pinnatis apicibus et in axillis pinnarum repetitum proliferis longissime extensis, pinnis 3-6 uncias longis sessilibus oblongo-lanceolatis acuminatis basi equalibus vel junioribus praeique inferne dilatato-rotundatis superne auriculatis integris vel (adultis) grosse crenato-serratis, venis pinnatis, venulis omnibus cum ipsis oppositis junctis et venas spurias intermedias formantibus, soris ovalibus copiosis, singulo in singula venula non raro confluentibus.

Polypodium proliferum, Roxb. Herb. Wall. Cat. n. 312, (not Kauffuss.)

Polypodium luxurians, Kze. in Linnaea, 23. p. 280.
Phlegopteris luxurians, Metten. Phleg. p. 25.

This is, doubtless, a very sportive plant, but its main feature is occasioned by its extraordinary tendency to send out new plants from axillary and terminal gemme, which take root, cover a great extent of ground, and hinder the real form and structure of the frond from being distinctly seen. One can hardly conceive, why so many names should have been adjudged to this plant, and even the honor of a new genus.

Fig. 1. Base of a pinna, seen from above.  f. 2. Base of a fertile pinna, seen from beneath.  f. 3. Portion of a fertile pinna, from near the middle, seen from beneath:—magnified.
Asplenium (Diplazium) Zeylanicum, Hook.

Caudice terete repente subterraneo nudo fibroso-radicante, stipitibus sparsis solitariis squamis laxis intense fuscis lanceolato-subulatis paleaceis 4-uncias ad spithamaeam longis, frondibus lanceolatis acuminatis subcoriaceo-membranaceis spithameis ad pedalem 1-2-uncialibus latis profunde pinnatifidis basi pinnatis spice subintegris serratisve, lobis pinnisque patentibus oblongis obtusissimis integerrimis, venis remotis furcatis, soris linearibus, involucris venula basi superiore loborum precipue diplazioides.

Hab. Ceylon, banks of a large stream of Kotmalee Oija, elev. 4,000 feet, Gardner, n. 1249. I have received a specimen also, from Mr. Thwaites, but possibly from Mr. Gardner’s collection.

I possess only two specimens of this distinct looking diplazioid Asplenium, and venture to constitute a species of it though it may possibly be a young form (yet in very good fructification) of some compound species, which time, and further researches only can show.

Fig. 1. Sterile lobe. f. 2. Fertile lobe:—magnified.
Asplenium (Diplazium) Lobbianum, Hook.

Fronde sesquipedali ovato-acuminata subcoriaceo-membranacea pinnata, pinnis 5-6-uncias longis 1\(\frac{1}{2}\) unciam latis petiolatis patentibus oblongis acuminatis paululum falcatis basi superiore truncata rachi parallela rarius subauriculatis, inferiore cuneata vel subrotundata marginibus serratis, pinnis supremis sensim minoribus confluentibus, venis subhorizontalibus fasciculatis 1-terve dichotomis, soris solitariis (asplenioideis) vel geminatis (diplazioideis) non raro subscolopendriodeis nec costam nec marginem attingentibus.

Hab. Java, Thos. Lobb. 1846.

This may possibly be included among the 12 species of pinnated Diplazium of Java, enumerated by Blume: but the characters of that author are so very brief, and unaccompanied by figures, which are such great helps in critical species, that I had better avoid all allusion to them, and content myself with saying, that among my own numerous diplazioid Asplenia, there is none to which I can refer this:—nor can I find that it corresponds with any one known to me of other countries.

I possess but one frond, and that without caudex or stipes.

Fig. 1. Lowest pinna, nat. size. f. 2. Portion of a fertile pinna, magnified.
Asplenium (Diplazium) crassidens, Fée.

Stipite stamineo-fusco spithamæo nudo, frondc subpedali coriaceo-membranacea atro-viridi subtus pallidiore opaca pinnata, pinnis paucis remotis 10-11 brevi-petiolatis patentibus remotis 4-uncialibus inæqualiterali-ovato-lanceolatis basi oblique attenuato-cuneatis subito acuminatis subgrosse serratis præcipue supra medium, supremis subdecurrentisessilibus ultimis tribus in unica hastiformi confluentibus, venis approximatis furcatis v. bis-terve dichotomis magis ramosis in pinna terminali, soris obliquis parallelis æqualibus e costa ad marginem atingentibus non raro præcipue ad apicem frondis diplazioideis, involucris fuscis. 

Hab. N. Grenada, Paramos of Ocaña, elev. 10,000 feet, Schlim, n. 393.

A peculiar looking species, with a costa dividing the pinna into 2 unequal portions, the upper half being the broadest. It is remarkable for the great regularity and length of the brown sori, extending, as they do, from the costa to the margin.

Fig. 1. Terminal fertile pinna seen from beneath:—nat. size. f. 2. Portion of the same with sori:—magnified.
Asplenum (Diplazium) fraxinifolium, Wall.

Caudice crasso declinato vix repente copiose crasse fibroso apice nigro-paleaceo, stipitibus aggregatis supe pedalibus fuscis subrubustis parte inferiori praeputpe laxe et deciduo nigrescente-palaeis, frondibus pedalibus ad sesquipedalem subeiraeaeis armis subnitentibus siccitate fuscis pinnatis, pinnis remotis 3-11 petiolatis patentibus 6-8-10-unicaulis late oblongo-lanceolatis tenui-acuminatis integerrimis basi suboblique cuneatis, venis fasciculatis bis terve dichotomis parallelis copiosis omnibus libris, soris copiosis lineari-clongatis a costa fere ad marginem continuas, involucris angustis.

Asplenium fraxinifolium, Wall. Cat. n. 194. 
Diplazium fraxinifolium, Wall. Herb. 1823. Moore, Index Fil. p. 133.

This fine Fern has been largely distributed by the late Dr. Wallich, under the name of Asplenium (Diplazium) fraxinifolium; and I am desirous of making it known to the botanical world; for as far as I am aware, it has been noticed by no Fern-author in any way, save that, in Moore’s Index Filicum, Wallich’s Asplenium fraxinifolium is called “Diplazium fraxinifolium.” My impression is that this Fern, with its free venation will prove specifically identical with Diplazium (Oxygonium) elegans, figured in Hook. t. 939-940, notwithstanding the anastomosing venation of the latter. I would observe, too, that the Diplazium alternifolium, Bl. (and Hook. Fil. Exot. Tab. 17) has, though possessing much broader pinnae, great affinity with this; but the whole group of diplazioid Asplenia require a careful study and revision, which we trust to attempt ere long.

Fig. 1. Portion of a fertile frond seen from beneath:—magnified.
Parvum, caudice filiformi repente hic illic inferne radiculoso, stipitibus subfasciculatis 3-4 ex eodem puncto 1½ unciam longis nudis gracilibus herbaceis supernae una cum rachibus marginato-alatis, frondibus 2½-3½ uncias longis submembra-naceis atroviridibus lanceolatis pinnatis, pinnis 6—9-jugis horizontaliter patentibus sublonge petiolatis oblique ovatis pinnatifido-lobatis basi inferne cuneato-incisis, lobis obtusis integerrimis basi superiore lobo majore auriculaeformi bi-trifido, venis simplicibus vel (in auriculam) bi-trifurcatis apice intra marginem clavatis, soris majusculis oblongis, involucro membranaceo latiusculo.

Asplenium Quitense, Hook. Spec. Fil. vol. 3. ined.

Hab. On decayed trees in the forest of Archedona, Quitinian Andes. Prof. W. Jameson, n. 707.

I refer this distinct and very pretty Fern, to the Trichomanes—division of Euasplenium, and it has some affinity with several of the less rigid, herbaceous species of that section; but is peculiar in the slightly winged rachis, the very distinctly petiolated, rather deeply pinnatifid, lobate pinnae, and, above all, in the long filiform creeping caudex.

Fig. 1. Sterile pinna. f. 2. Fertile pinna, seen from beneath. f. 3. Portion of a pinna, with sorus:—all magnified.
Caudice "repente sublignosö," stipitibus solitariis erectis flexuosis pilis setisve ferrugincis patentibus hispidissimis, frondibus digitalibus ad drorantalem lato-lanceolatis acuminatis rigido-subcoriaceis sparse setaceo-pilosis, pinnis primariis remotiusculis 2-pollicaribus lineari-acuminatis patentibus, pinnulis 1½ lineam longis sessilibus linearibus acutiusculis integerrimis inferne subdecurrentibus univenis, venis dimidia pinmarum longitudine apice clavatis, soris solitariis globosis ad basin venarum insertis, rachi compressa.

Polypodium myriophyllum, Mett. l. c. p. 6.

Hab. In clefts of rocks and on old trees, on the lofty mountains of Java, Blume. Trunks of trees, near Tatanara, Peru, Lechler.

The only localities known of this elegant and rare species of Polypodium, are the high mountains of Java, and those of the Peruvian Andes. I possess, indeed, only Peruvian specimens; but they quite accord with Blume's figure.

Fig. 1. Portion of a fertile pinna with pinnules. f, 2. Sterile pinna:—magnified.
Asplenium (Euasplenium) Gibertianum, Hook.

Caudice crasso descendente copiose radiculoso superne setos-squamoso, stipitis numerosis caespitosis vix unciam longis compressis viridibus demum dorso præcipue castaneis su-perne alatis, frondibus subsemipedalibus lanceolatis mem-branaceis pulchre viridibus pinnatis, pinnis numerosis approx-imatis \( \frac{1}{3} \) -unciam longis patentibus ovato-lanceolatis pro-funde pinnatifidis sessilibus basi oblique cuneatis et in alam laterisculam longe (usque ad insertionem) pinnae adjacentis inferioris profunde pinnatifidis, lobis oblongo-lanceolatis acutissimis integerrimis inferneus subscuriris biquadrifidis pinnis infinis subifabelliformibus, venis simplicibus vel in lacinis 2—4-fidis bi-furcatis, soris oblongis discoidalibus (e margine ct costa remotinsculis), involucro membranaceo albido, rachi insigniter compressa herbacea apice sapius longe excurrente prolifer.

Asplenium inciso-alatum, Moore, MS. in Herb. Hook. and in Index Fil. p. 137. (name only).

Hab. Assumption, State of Paraguay, (not Island of Assumption, as given by Mr. Moore), M. Gibert.

A very delicate and beautiful species, of which I have seen only one fine specimen, kindly sent me by M. Gibert, a gentleman chiefly resident at Monte Video, but who has contributed much to our knowledge of the Nat. History of Paraguay, and to whom I desire to dedicate the species. It belonging to a family of plants, of which there are comparatively few representatives in Paraguay, judging from the proportion of them with other plants that have yet come to us. It will rank near the well-known Aspl. cicutarium.

Fig. 1. Sterile pinna and winged rachis. f. 2. Fertile pinna and winged rachis. f. 3. Bifid segments of a pinna and sorus:—magnified.
DAVALLIA (CUNEATAE) GOUDOTIANA, Kze.

Pumila, caudice repente gracili, stipitibus remotis solitariis unciam sesquiounciam longis gracilibus basi parce squamosis, frondibus 3-4-uncialibus lanceolatis paululum acuminatis membranaceis pinnatis glaberrimis, pinnis subsessilibus profunde subtripinnatifsidis unciam longis, laciniiis omnibus cuneatis integris vel bisidas obtusis, venis seu costis simplicibus v furcatis, soris solitariis in apicibus segmentorum utrinque vel uno latere dente instructis involucrum paullo excedente, involucris reniformibus bivalvis.

Davallia Goudotiana, Kze. in Annal. Pterid. p. 35. t. 22. f. 2. Hook. Sp. Fil. 1. p. 188. tab. L. C.

Hab. Madagascar, Goudot, Dr. Lyall, and Bojer, in Herb. Nostr.

Having received from the late Professor Bojer of Mauritius, more perfect specimens than I was possessed of, when publishing the first vol. of my "Species Filicum," I gladly publish figures of them on the present occasion.

Fig. 1. Portion of a fertile frond. f. 2. Segments with sori and involucres:—magnified.
Polypodium (Phegopteris) dareaforme, Hook.

Caudice crassiusculo brevi subrepente dense ferrugineo-paleaceo squamis lanceolatis acuminatissimis, stipite 4-unciali nitido pallide castaneo, fronde spithamæa ovato-deltoida submembranacea bipinnata, pinnis primariis 4-5 uncias longis 1¼ uncam latis oblongo-lanceolatis subsessilibus acuminatis, pinnis oblongo-ovatis subbipinnatifidis laciniiis obovato-linearibus obtusissimis simplicibus vel bifidis, venis seu costis in divisionibus solitariis ante apicem terminantibus clavatis, soris solitariis parvis ad basin laciniarum ultimarum, capsule in utroque soro perpaucis.

Hab. Khasya hill, Simons, n. 98.

This finely cut Polypodium has some affinity with Polypodium temnisectum, Bl. and perhaps, still more, with Blume's P. millefolium, but besides other characters, the form of the two is quite different, and the ramification is much more compound.

Fig. 1. Secondary pinna with sori. f. 2. Portion of a pinna. f. 3. an ultimate segment with a sorus, from which most of the few capsules are removed:—magnified.
Aspidium (Polystichum) Thomson; Hook.

Caudice brevi crasso obliquo apice squamoso, stipitibus basi insigniter squamosis 3-4-uncialibus gracilibus stramineis una cum rachi straminea sectoso-paleacea, frondibus digitalibus ad spathaeam lanceolatis acuminatis subchartaceo-membranaceis sessilibus pinnatis, pinnis 3-4 lineas longis sessilibus ovatis profunde pinnatifidis præcipue ad marginem superiorem vel bipinnatis, pinnulis ovatis lobisque spinulo-incisis serratisve, venis pinnatis venulis ultimis clavatis, soris solitariis in singula pinnula seu lobo majusculis dorso venula insertis, involucro subovato membranaceo peltato pedicellato margine sæpe eroso.

This must rank among the smallest of the Polystichum-group of Aspidium, approaching nearest to the smallest specimens of Dr. Wallich's Aspid. (Polystichum) oxyphyllum. The involucre, if constant to its form and pedicel, is very remarkable.

Fig. 1. Fertile pinna, almost again pinnate. f. 2. Portion with sori. f. 3-4. Involucres: magnified.
Acrostichus (Gymnopteris) Linnaeanum, Hook.

Caudice repente squamoso subtus fibroso, stipitibus sparsi approximatis 2-6-unzialibus inferne squamis nigris subulatis paree palaeosis, frondibus subdimorphis; sterilibus 4-8 uncialibus longis semiumlcan latis submembranaceis elongato-lanceolatis subopaciis superne sephe longe acuminatis apice radicans et proliferis margine integerrimis, venis indistincte pinnatis, venulis primariis transversis secundarisque varie anastomosantibus, areolis majusculis subhexagonis rarissimo appendiculatis, stipitibus 2-3 uncialibus longis; fertilibus duplo angustioribus rigidioribus 4-unzialibus lineari-lanceolatis.

Leptochilus Linnaeansus, Fée, Acrostich. p. 87. tab. 47. f. 2. excluding probably all the synonyms; certainly all references to figures.

Dendroglossa Linnaean, Fée, Gen. Fil. p. 81.

Hab. Malay Islands, Java, "Zollinger, n. 1441." Borneo, Motley, n. 427.

There can, I think, be no doubt of this pretty Fern being the Leptochilus Linnaeansus of Fée, l. c.; but he quotes Linnaeus' Acrostichum lanceolatum, Amoen. Acad. 1. p. 268; though it is quite clear that Linnaeus had quite another Fern in view, since he says of it, in Sp. Plant p. 1523, "fructificationes sunt puncta confertissima, versus apicem frondis," and he refers to Hort. Malab. 12. t. 27. But Swartz, long ago, showed that the Linnaean plant was the Polypodium acrostichoides of Forst. Prodr. now generally referred to Niphobolus.

Fée afterwards in his Genera Filicum refers Linnaeus' Acrostichum lanceolatum to Dendroglossa; while Moore places it in his Gymnopteris, among the Pleurogrammeæ.

Fig. 1. Portion of a sterile frond to show the venation, (where however, the primary pinnated veins are scarcely sufficiently distinctly represented). f. 2. Portion of a fertile frond seen from beneath, one side with the capsules removed. f. 3., Capsule: magnified.
Caudicæ longæ repente paleaceo-squamoso radicante, fibris longīs flexuosis, stipitis numerosis sparsis gracilibus 2-4 ounias longīs inferne squamis ovatis fuseis paleaceis, frondibus 4-6 ounias longīs late ovato-lanceolātīs membranaceis fuscīdīs bipinnatīs siccatīte atro-viridībus pinnīs (16-17) 1-1 ½ ouniam longīs horizontalīter patentībus remotisculis lanceolātīs basi pinnatis apicem versus pinnatifidīs, pinnulis 3-5 parvis 2-3 lineas longīs petiolulātīs obovato-subrhomboideis obtusīs nune profunde trilobīs lobis obovatis dentatis, venis furcatīs, soris paucīs oblongīs parvis, involucris brunneīs laxe membranaceīs subathyroidēs, mehī gracili subflexuosa.

Hab. Jamaica, MacFadyen.

Some years ago I had the pleasure to receive this new Fern from my late friend Dr. MacFadyen, and only upon that one occasion. It may therefore be considered a rare Asplenium, and assuredly a very distinct one, not likely to be confounded with any other.

Fertile plant:—nat. size. Fig. 1. Superior basal pinna: magnified. Fig. 2. Sorus: more magnified.
Asplenium (Euasplenium) elegantulum, Hook.

Caudice (aetate) subrobusto horizontali vel declinato ad apicem paleaeo squamulis subulatis fuseis, stipitibus aggregatis brevibus 1-2-3-uncialibus subchloro submarginata viridibus, frondibus 4-pollicariis ad spithamseam elongato-lanceolatis acuminitatis membranaceis flavo-viridibus bipinnatis inferne augustatis eum pinnis nanis flabelli-vel reniformibus, reliquis 1 3 ad unciam longis ovatis seu ovato-lanceolatis subsessiibus iterum pinnatis basin versus praeipue apice pinnatifidis, pinnulis ovatis subhomboides obvatisve 1-1 1/2 lineam longis acutae denticulato-serratis, venis furcatis subpatentibus in pinnis inferioris subflabellatis, soris copiosis demum confluentibus, involucris pallidis oblongis laxis subathyroidis.

Hab. Island near Chusan, Alexander; Port Hamilton, and Tsus Sima, Strait of Korea, Wilford, n. 753; Japan; Nangasaki, Miss Nelson, Babington; Hakodadi, Dr. Baines; Simoda, C. Wright.

Late events have contributed to the opening up to us of the Botany of N. China and Japan, whose geographical position naturally led us to expect European forms of Ferns. The present species was at first considered by me to be a state of Aspl. lanceolatum, while Mr. Eaton looked upon it as more related to Aspl. fontanum. More copious specimens have satisfied me it is truly distinct from both. The young fronds are simply and closely pinnated, with obliquely ovate pinnae.

Fertile Fronds:—nat size. Fig. 1. Pinnule, and f. 2. Sorus: magnified.
Asplenium (Euasplenium) tenuifolium, *Don.*

Caudice horizontali erassineculo etate vix paeneaco, stipitibus caspitosis 3-4 uncias ad spithameam longis ad basin castaneis, frondibus oblongo-ovatis acuminatis pallide vi-ridibus membranaceis 6-12 uncias longis 3-pinnatis, pinnulis pinnulisque petiolaris, pinnis primariis 2-3 uncias longis patentibus lato-lanceolatis acuminatis, pinnulis ultimis obovato-v-lineari-cuneatis bi-trifidis laciniatisve, segmentis acutissimis subspinulosis, frondis pinnarumque apicibus pinnatifidis segmentis linearibus, venis in segmentis solitariis longe ante apicem terminantibus, soris solitariis vel binis in quaque segmento.

*Asplenium concinnum,* *Wall.* *Cat.* n. 216.

An elegant, very compound species, sometimes almost quadripinnate, allied to the West Indian *Aspl. cicutarium,* yet very distinct, especially in the very acute segments of the pinnules, and in the involucres never opening at or near the margin.

Fertile Plant:—*nat. size.* *Fig.* 1. pinnule. • *f.* 2. Sorus: magnified.
Asplenium (Euasplenium) Hallii, Hook.

Caudicé erassiuscelo asecentente, stipitibus caespitosis ebeneis nitidis 1-2 uneias longis, frondibus 6-12 uneias longis submembranaceis fuso-viridibus oblongis lanceolatisve basi attenuatis apicé longe acuminatis flagelliformibus subappulatis radicantibus subbipinnatis seu pinnato-pinnatifidis, pinnis primarias sessilibus ovato-lanceolatis obtusis 3/4 ad uneiam longis horizontalibus subpectinato-pinnatifidis, segmentis linearibus obtusis ad basin superiorem subauriculatis bifiidis vel inferne iterum pinnatis, pinnis inaequalibus frondis minus, venas pinnatis solitariis in quoque segmento, sori parvis oblongis costam versus, involucri membranaceis, raehi ebenea.

Asplenium pectinatum, Moore, mst. in Herb. Hook. et in Ind. Fil. (name only) not of Wallich, nor of Mettenius.

Hab. Forest of Esmeraldas, Ecuador, Col. Hall; Sao Gabriel, valley of the Amazon, on young trees and shrubs, "fronds spreading horizontally," (no doubt rooting at the extremity), Spruce, n. 2357.

No other stations than the above have yet been recorded for this rare species. In the flagelliform and radicant apex it resembles Aspl. rhizophyllum, but the pinnae and pinnules are widely different. It is remarkable for the ebeneous short stipes and rachis, and the dwarfed lower pinnae extending almost to the caudex.

Fertile plant: nat. size. Fig. 1. portion of a bipinnate form: nat. size. f. 2. primary pinna, fertile, and f. 3. involucre: magnified.

Cf. 2. 2. 20.
Parvum, caudice longe filiformi ramoso hirsuto-tomentoso, stipitibus sparsis remotis vix 2 lineas longis, frondibus sub-biunialibus ovato-lanceolatis bi-rarius tripinnatis, pinnis 2 lineas longis petiolatis, pinnulis divaricato-patentibus vix lineam longis euneato-palmatis in petiolulum attenuatis apie irregulariter subdigitato-laciniatis, venis crassiusculis immersis simplieibus vel furcatis longe ante apicum terminantibus elevatis, soris semiovatis solitariis, involucris membranaceis fuscis, raei stipiteque herbaceis.

**Hab.** Ecuador, growing on trees and shrubs in the forests of Archedona, Quitinian Andes, *Jameson, n. 786.*

One of the most distinct of all *Aspenia*. The filiform caudices are a foot and more long; yet the fronds are among the smallest of the Genus, and the pinnules of the fronds are in shape more like some *Plagiochilus* among *Jungermannia* than any Fern I know. The veins terminate far below the apex of the segment, and the involucres are all remote from the margin.

Portion of a fertile plant: *nat. size.* *Fig. 1 & 2.* Pinnæ, with and without sori. *f. 3.* sorus: *magnified.*
**Onychium strictum, Kze.**

Caudice subfusiformi tuberculato obliquo apice radicoso, sti-
pitibus caspitosis spithamaeis ad pedalem rachibusque stra-
mineis inferne parce palaeaeis, frondibus subsithamaeis fere
membranaceis viridis glabras opacis subdeltoideo-ovatis
3-4-pinnatis seu pinnatiseetis, segmentis lineari-subcuneatis
acutis sepe oppositis integris v. bitrifidis, rachibus angustae
achtis, fertilibus paulo latioribus, soris brevibus sub-oblongis
obtusis curvatis ante apicem sitis rarius solitariis.

Onychium strictum, Kunze, in Schk. *Fil. Suppl.* 2. p. 11,

**Hab.** St. Jago de Cuba, on Mount Leban, Linden, *n.* 1870,
C. Wright, *n.* 858.

With the exception of the present species, and *Onychium
angustifolium* Kze. (our *Pellcea decomposita*, *v.* 2. *p.* 171) all
the true *Onychia* are natives of the Old World. Here how-
ever it may be observed that the sori are less decidedly in
exactly opposite pairs than is consistent with the character
of the Genus. It borders too closely on *Cheilanthes*, as that
does again on *Adiantum*.

Fertile plant: *nat. size.*  **Fig. 1.** Portion of a pinna with
sori: *magnified.*
Asplenium (Euasplenium) Wardii, Hook.

Caudice subhorizontali erassiusculo superne squamis longis subulatis dense vestito, stipitibus eæspitosis spithamaeis stramineis inferne parce subulato-squamosis, frondibus 12-14 uncias longis basi 10 uncias latis membranaceis deltoideo-acuminatis olivaceo-fuseis opacis bipinnatis apice pinnatifidis, pinnis horizontalibus petiolaris lanceolatis acuminatis, pinnulis approximatis 6-8 linea longis horizontalibus sessilibus subdimidiato-ovatis obtusis integerrimis v. laviter sinuatis serratisve, pinnarum inferiorum pinnulis subpinnatifidis auriculatisque superiorum subintegris decurrentibus, venis pinnatis oblique patentibus simplicibus fureatisve, soris biserialibus costam versus, involucris (junioribus) tenui-membranaceis pallidis.

Hab. Tsus Sima, Strait of Korea, Wilford, n. 717.

A very distinct Asplenium from any known to me, with more the habit of some Lastrea than is usually seen in this Genus. I name it in compliment to John Ward, Esq. Commander of H. M. S. "Actæon," in acknowledgment of his services rendered to Mr. Wilford, Botanical Collector for the Royal Gardens of Kew, during an interesting cruise in the North Chinese Seas, and as far as Manchuria.

Fertile plant: nat. size. Fig. 1. Pinnule with sori: magnified.
Asplenium (Euasplenium) rutaceum, Mett.

Caudice obliquo radicante, stipitibus cæspitosis brevissimis semiiuneiam ad duas uncias longis castaneis, frondibus 10-12 uncias longis membranaceis atro-viridis lato-lanceolatis basi sensim attenuatis apice in caudam longum filiformem ad extremitatem radicantem extensis bi-tripinnatis, pinnis primaris horizontalibus unciam sesquieunciam longis numerosis approximatis (infinis nanis) et basi latiuscula oblongis obtusis, secundariis 2 lineis longis omnibus petiolatis pinnatis, pinnulis 2-3 obovato-spathulatis subacutis integris v. bilobis, pinnulis infinis magis compositis summis integris vel bilobis minimis remotis, venis in quoque lobo indivisis longe infra apicem terminantibus apice clavatis, sori brevisbus ovalibus in disco sitis, involucris membranaceis pallidis.

Hab. St. Domingo, Plumier; Columbia, Tovar, Moritz, n. 402; New Grenada, Ocaña, Schlim n. 624; and Sierra Nevada, elev. 6000 feet; Venezuela, Fendler, n. 123; on trunks of trees, forests of Archedona, Andes of Quito, Jameson, n. 788.

An elegant species, lately well described by Mettenius, previously very incorrectly understood, and chiefly in consequence of Plumier's rather exaggerated figure above quoted, from which Willdenow's character appears to have been drawn up: and hence too he was led into the error of believing it to be an Aspidium.

Fertile plant; nat. size. Figs. 1 & 2. Pinnules with sori; magnified.
Scolopendrium (Camptosorus) Sibiricum, Hook.

Caudice parvo ascendentе radiculoso, stipitibus cæspitosis gracilibus 2-4-uncias longis, frondibus membranaceis, sterilibus brevibus oblono-ovatis acuminatis, fertilibus 5-6 uncialibus lanceolatis longissime caudatim attenuatis apice radicanibus, venis prope costam anastomosantibus reliquis liberis apicibus clavatis, soris geminatiis non raro sparsis solitariis.

Scolopendrium (Camptosorus) sibiricum, Hook. Sp. Fil. 3.

Hab. Siberia, River Angara, Steller; Kamtschatka, Georgi; Island of Tsus Sima, Strait of Korea, Wilford, n. 790.

Linnaeus gives “Siberia” as a locality for the N. American Asplenium (Camptosorus) rhizophyllum. The Siberian plant is however since acknowledged to be a new species, distinguished by the entire absence of lobes or auricles at the base of the frond, which are so characteristic of the United States. But even in Siberia the present species appears to be of very rare occurrence, insomuch that the late learned author of the Flora Rossica (Ledebour) was obliged to declare “species mibi ignota.” Only two stations for it have been yet recorded in all the Russian dominions; and now that it has been detected in the island of Tsus Sima, off the coast of Korea, the discoverer there accompanies his specimen by the remark “the only specimen found;” and that is the one here represented.

Camptosorus and Antigramme only differ from Scolopendrium by the partial anastomosing of the veins; in the former next the costa; in the latter next the margin. To me it seems most natural to unite both with Scolopendrium.

Fertile and barren fronds. Fig. 1. Portion of a sterile frond, showing the venation, and Fig. 2. portion of a fertile frond with sori: magnified.
Asplenium (Euasplenium) dimorphum, Kze.

Caudice ("repente crasso") stipitibus 6-12 uncias longis, frondis amplis 2-pedalibus et ultra chartaceo-membranaceis deltoido-ovatis bi-tripinnatis, pinnis ovato-lanceolatis petiolatis acuminatis biformibus in eadem fronde v. in frondibus diversis, inferioribus plerumque sterilibus simpliciter pinnatis, pinnulis rhombo-ovatis basi inequaliter cuneatis margine serratis sapa lobatis vel basin versus iterum pinnatis, venis pinnatis dichotomis; pinnis fertilibus plerumque terminalibus bipinnatis vel potius bipinnatis-fidis, laciniis linearibus angustis obtusis, venis costiformibus, soris plerumque solitariis dareiformibus ramis geminatis diplazioides.

Hab. Norfolk Island, and noewhere else as far as yet known.

One of the most distinct of asplenioid Ferns, and among the most limited in respect of country, for it appears to be confined to Norfolk Island.

Fig. 1. Portion of a frond, with sterile and fertile pinnæ; nat. size. f. 2. Sterile pinnule. f. 3. Fertile pinnule with sori: magnified.

Cent. 2. t. 36.
Asplenium (Euasplenium) scandens, J. Sm.

Caudice crassitie penne corvinae longe repente flexuoso ramoso parce radicante apicibus paleaceis, stipitibus sparsis remotis brevissimis, frondibus 1-2-pedalibus et ultra late ovato-lanceolatis basins versus attenuatis subcoriaceo-membranaceis olivaceo-viridibus 3-4-pinnatis, pinnis primariis horizontalibus 3-4-uncias longis lato-lanceolatis sessilibus numerosis subdistantibus, inferioribus nanis magis remotis, pinnis secundariis unciam longis, pinnulis ultimis seu la- ciniis 4-5-lineas longis anguste linearibus infinis superioribus furcatis vel trifidis reliquis integris acuis, fertilibus paululum latioribus, venis costaeformibus, soris marginalibus oblongis, involucris firmis submembranaceis pallide fuscis; rachibus primariis teretibus, partialibus compressis su- balatis.

Hab. Philippine Islands, Leyte, Cuming. n. 297; New Guinea, Hinds.

A rare and well-marked species, remarkable for its long creeping, or perhaps, scendent caudex.

Fig. 1. Caudex and small frond. f. 2. Portion of a larger and fertile frond; nat. size. f. 3. Sorus: magnified.
Asplenium (Euasplenium) ferulaceum, Moore.

Caudice? stipite 14 uncias longo robusto pallide fusco hinc sulcato, fronde sesquipedali supradecomposita (4-5-pinnata) late viridi membranea deltoideo-ovata acuminata, pinnis primariis numerosis subdistantibus inferioribus 6-8 uncias longis petiolatis late ovatis aeuminatis, secundariis 3 uncias longis, ultimis brevibus lineam longis lineari-subspathulatis mono-rarius disoris, venis costaeformibus, soris parvis darcioideis, involueris viridescensibus submembranaceis, rachibus primariis secundariisque teretibus stramineis nitidis ultimis augustissimis compressis glabris.

Asplenium ferulaceum, Hook Sp Fil. 3. p. 216. Moore. Mss. in Herb. Nostr. Moore, Ind. Fil. p. 130. (name only, no character or description.)

A very distinct and elegant, and hitherto undescribed species, of the Darea-group, remarkable for the very compound, or rather decompound, finely cut pinnae, and the terete primary and secondary rachises, which are stramineous and glossy.

Fig. 1. Stipes and base of a lower primary pinna. f. 2. A superior primary pinna; nat. size. f. 3. Pinnule with sori: magnified.
Asplenium (Euasplenum) dichotomum, Hook.

Parvum, caudice erecto submullo radicante paleacco, stipitibus easpitosus subuneciam longis graelibus compressis pallide viridibus setaceo-paleacess, frondibus 3-4-uncialibus ob-longis acutis membranaceis viridibus subtripinnatis, pinnis primariis $\frac{1}{2}$-3 unciam longis subdimidiato-ovatis subapproximatis petiolatis dichotomic divis, pinnulis brevibus angustis linearibus bis-terve dichotomis, segmentis fertili-bus paulo latioribus, venis solitariis costiformibus, soris magnis lineari-oblongis marginalibus dareoideis, rachibus omnibus compresso-alatis.

HAB. Borneo, Hugh Low, Jun., Esq.; Lobouk Peak. clev. 5,000 feet, north-east side of Borneo, Thos. Lobb.

This would be a true Darea (or Ceratopteris,) in the view of those botanists who adopt that genius; but I know none with which it is likely to be confounded. It is a small and extremely delicate species, the whole height scarcely exceeding 4 inches.

Fertile plant; nat. size. Fig. 1. Pinna with soris. f. 2. Single sorus: magnified.
Asplenium (Euasplenium) davallioides, *Hook*.

Caudice parvo suberecto supra squamoso, stipitibus caespitosis 3-4 uncias longis compressis deciduo squamosis, frondibus 3-6-uncias longis subcoriaceis ovatis acuminatis 3-sub-quadruplicatis (junioribus primariis pinnis lobato-pinnatifidis), pinnis primariis 2-3 uncias longis petiolatis, secundariis petiolatis $\frac{1}{4}$ unciam longis late ovatis, pinnulis ultimis parvis oblongis acutis simplicibus vel bifidis, segmentis omnibus patenti-recursis acutis, venis costiformibus, sori oblongis sepissime marginalibus longitudine fere segmentorum, involucris membranaceis firmis, rachibus alato-compressis.

*Hab.* Nangasaki, Japan, Babington, n. 101; Loochoo Islands, C. Wright; Tsus Sima, Strait of Korea, Wilford, n. 791.

A species which cannot easily be mistaken for any other of the group to which it belongs, if the short and singularly divergent or patenti-recurved ultimate segments be considered, with the sori, though short in themselves, nearly as long as the ultimate segments, and giving the appearance of a dareoid species of *Davallia*.

Asplenium (Euasplenium) Monteverdense, Hook.

Caudice parvo fibroso-radicante, stipitibus caespitosis 1-2 uncias longis lurido-castaneis, frondibus 4-6 uncias longis lato-lanceolatis acuminatis inferne attenuatis membranaceis pallide viridibus demum subcoriaceis atro-viridibus tripinnatis, pinnis omnibus subpetiolatis, primariis patentibus 1-1½ unciam longis oblongo-ovatis obtusis, secundariis lato-cuneatis (infimis brevibus pauci-pinnatis) plerosisque bi-trifidis segmentis brevibus acutis modice subincurvis, venis costaformibus apice clavatis, soris in lobos solitariis vix dareoides, involucris parvis lineari-oblongis flavo-virescentibus valde membranaceis, rachibus viridibus compressis marginatis.

Hab. Under overhanging rocks near Mount Verde, on the eastern side of Cuba, C. Wight. n. 1029.

Of this species the affinity is perhaps with Aspl. varians, Hook. & Grev., but the very short stipites, the fronds attenuated at the base, the different form of the pinnae and their more distinct petioles will readily distinguish it; or, more nearly, with some of the many forms of Aspl. cicutarium. In the old state of fructification the plant might be taken for a Gymnogramme, for the eopious capsules soon cover and conceal the involucres.

Fertile fronds; nat. size. Fig. 1. Pinnule with sori. f. 3. Single sorus: magnified.

Tab. XLI.
**Aspleniun (Euaspleniun) Prolongatum, Hook.**

*Candice parvo ascendente radicante vix squamoso, stipitibus cespitosis 2-4 uncias longis stramineis subcompressis, frondibus 4-5-uncialibus ad pedalem coriaceis seu subchartaceis oblongis vel lineari-oblongis sepe falcatis bi-subtripinnatis, rachi apiee prolongata caudiformi nuda radicante 1-2 uncias longa, pinnis primaris 1-1½ uncias longis horizontaliter patentibus sepe approximatis semiovatis obtusis petiolatis semipinnatis (seu pinnulis hinc longioribus numerosioribus), pinnulis 3-4 lineas longis plerisque simplicibus integris raro furcatis ad basin superiorem bi-tripartitis, venis costiformibus, soris oblongis submarginalibus, involucris firmis membranaceis eolore frondis.*

A very elegant and well marked species, retaining its characteristic distinctions in all the specimens from the several localities above mentioned. Nearly every one exhibits the remarkable prolongation of the rachis, rooting at the apex and often very proliferous there. Of the primary pinnae the longest and most numerous pinnules are always on the upper half.

Fertile plant; *nat. size.* *Fig. 1.* Pinna. *f.* 2. Sorus: magnified.
Asplenium (Athyrium) medium, Carm.

Caudice "6-7 uncias longo," stipitibus 5-6 unciam longis stramineis basin versus incrassatis paleis longissimis angustissimis ferrugineis flexuosis obsoitis, frondibus spathameis rigide subcoriaceis deltoideis acutis bipinnatis, pinnis sæpe oppositis horizontalibus approximatis sessilibus 3 uncias longis ovato-lanceolatis, pinnulis $\frac{1}{2}$-$\frac{2}{3}$ unciam longis lato-lanceolatis sessilibus pinnatifidis acutis vix auriculatis segmentis ovato-oblongis serratis, venis pinnatis diehotomis, soris copiosis, involucris membranaceis reniformibus sinuatis margine crosis, rachi universali crinita.

Aspidium medium, Carm. in. Linn. Trans. 12. p. 311.

Hab. Tristan d’Acunha, on the Table-land; Dr. Carmichael, in Herb. nostr.

A very distinct species, peculiar, as far as yet known to the island just mentioned. Its discoverer has noted, "stem (caudex) about 6 inches high, crowned with a circle of fronds from 9 to 12 inches high."

Fertile plant; nat. size. Fig. 1. Pinnule with sori. f. 2. Single sorus. f. 3. Setiform scale from the stipes: magnified.
Asplenium (Athyrium) Nigritianum, *Hook.*

Tota planta siecitate nigra, caudice brevi robusto erecto squamis copiosis atro-ferrugineis subulatis paleaceo, stipitis caespitosis robustis spithamaeis rachique dense fusco-villoso, frondibus 1-1½ pedem longis rigide coriaceis oblongo-lanceolatis acuminatis basi attenuatis bi-tripinnatis, pinnis remotis, reliquis magis approximatis horizontalibus 2½ vix 3 uncias longis lanceolatis acuminatis, pinnulis 2-3-lineas longis omnibus petiolulatis oblique rhomboideis obscure et obtuse auriculatius seu inaequaliter bilobis serratis, pinnulis remotis ternatis seu subpinnatis rachin imbricantibus, venis obscuris subflabellatis dichotomis, soris 1-5 in singula pinnula parvis lato-oblongis, involucris convexis integerrimis fere nigris.

A distinct and very peculiar *Asplenium*, which has no near relationship to any species known to me; remarkable for its firm, rigid texture, very stout stipes and main rachis, shaggy with woolly, hair-like scales, and for the very black colour of the whole plant when dry. I place it with some hesitation among *Athyria*, on account of a certain peculiarity of habit, and of the convex involucres, which however are very firm and coriaceous, and nearly of the same colour as the (dried) frond.

Portion of the base and apex of a fertile plant; *nat. size.* *Fig. 1.* Inferior pinnule from a sterile pinna. *f. 2.* Fertile pinna with sori: *magnified.*
Asplenium (Eudiplazium) Thwaitesii, A. Braun.

Caudice longo repente atro radicante, stipitibus sparsis 4 uncias ad spithameam longis rachique pilis crispatis squamisque lanceolatis membranaccis vestitis, frondibus spithamecis ad pedalem ovato-lanceolatis acuminatissimis membranaceis pinnatis apice pinnatifidis, pinnis 1½-3 uncias longis approximatis sessilibus horizontalibus obtusis rectis profunde frecr ad rachin pinnatifidis, lobis brevi-oblongis obtusis apice dentatis, venis pinnatis simplicibus v. fureatis, sors singulo lobo in sieribus duabus parvis lincari-oblongis, involucris pallide fusces membranaceis convexis suberosis nunc diplazioidesis, costis et venis supra subglandulososparsae pilosis.

Hab. Ceylon, Gardner, n. 1343, Thwaites.

A remarkable and well defined species in its long, creeping, subterranean, blackened caudex, and the densely tomentose and peleaceous stipites and main rachises.

Fertile frond; nat. size. Fig. 1. 2. 3. Portions of pinnae with sori: magnified.
Asplenium (Eudiplazium) vestitum, Hook.

Hab. Isle of Samar, Philippines, Cuming. n. 336.

Our younger specimens, as they appear to be (yet bearing copious sori), are simply pinnated, the larger and older ones bipinnate, with large very distant primary pinnae.

Fig. 1. Stipes. f. 2. Portion of a fertile frond; nat. size.

f. 3. Portion of a fertile pinna, with sori. f. 4. Scale from the base of the stipes: magnified.
Davallia (Saccoloma?) Denhami, Hook.

Caudic repente subulato-paleaceo, stipitibus subsparsis 3-6 uncias longis castaneis nitudis, frondibus 6-8 uncias longis subchartaeis ovatis acuminatis bipinnatis, pinnis petioltatis 2-3 uncias longis lanceolatis acuminatis remotis, pinnulis semiunciam ad unciam longis lineari-lanceolatis obtusis pinnatifidis basi sessilibus subdecurrentibus, laciniis brevis-simis 1-bidentatis monosoris, involucro pyriformi parte superiore libera rotundata.

A very pretty new Davallia, which, like the following one (D. rhomboidea, Tab. xlviii), I find difficult to refer satisfactorily to its group in the genus; so much do those groups gradually pass, by almost insensible characters, into others.

Fertile plant; nat. size. Fig. 1. Small pinnule with sori. f. 2. Sorus. f. 3. Sorus with the anterior portion of the involucre removed: magnified.
Davallia (Cuneatæ) rhomboidea, Hook. (not Wall.)

Caudice gracili elongato repente atro nitidissimo fragili, stipitibus sparsis 3-4 uncias longis stramineis nitidis basi ebenis, frondibus 6-8 uncias longis oblongo-lanceolatis aenuminatis tenui-membranaceis pallide viridibus pinnatis, pinnis patentibus inferioribus remotis subunciam longis rhombo-subtriangularibus longe petiolatis profunde pinnatifidis subpinnatisque lobis pinnulisve oblique obovatis inaequaliter lobatis, sterilibus serrulatis, yenis subflabellatis dichotomis apice soriferis, involucris orbiculari-cuneatis membranaceis apice erosâ solummodo libera lobulis frondium marginis conformibus, rachibus gracilibus subflexuosis, pinnis suprernis sublanceolatis.

Hab. Hakodadi, Japan, Wilford, n. 1037.

A very elegant and peculiar species of Davallia, which I am disposed to refer to the section Cuneatæ; it is quite different from any described one, and only known to us through our collector, Mr. Wilford.

Fertile plant; nat. size. **Fig. 1.** Portion of a pinna with sori; **magnified.** f. 2. Sori more magnified, one representing the involucrum removed; **more magnified.**

Cent. 2. t. 48.
Polypodium (Phegopteris) decursivo-pinnatum,
Van Hall.

Caudice subrepente stipitibusque semipedalibus stramineis
squamis subulatis ciliatis ferrugineis paleaceis, frondibus
villosoleis pedalibus et ultra lanceolatis tenui-acuminatis
inferne augustatis pinnatis apice pinnatifidis, pinnis
horizontaliter patentibus oblongo-lanceolatis pinnatifidis,
infinis brevibus libinis, reliquis libido intermedio semicirculari
coadunatis, venis pinnatis apice clavatis supra medium so-
rieris, sors perpauci solitarii parvis pilis fasciulatis cap-
sulis duplo longioribus (vix basi in membranam seu involu-
crum unitis) intermixtis, rachibus stramineis nitidis patenti-
ferruginco-villosis.

Polypodium decursivo-pinnatum, "Van Hall in N. Verhandl.

(fragments only.)

Aspid. p. 75.

HAB. Japan, Goring; Port Chusan, Korea, Wilford, n. 920.

A very elegant and very distinct species allied to the Euro-
pean Polypodium Phegopteris, Linn. and to the Pol. hexagonop-
terum, Sw. but very different in form and in the presence
of the copious, spreading, ferruginous, subulate scales which
clothe the stipites and rachis. Kunze and others consider
that the hairs of the sori arise from an almost obsolete invo-
lucre, and hence they refer the plant to Aspidiaceae.

Tab. XLIX. Fertile plant; nat. size. Fig. 1. Portion of a
fertile pinna. f. 2. Sorus. f. 3. Scale from the base of the
stipes: magnified.
Adiantum monochlamys, Eaton.

Caudice horizontali fusco-tomentoso, stipitibus spithamensis rachibusque flexuosis castaneis nitidis, frondibus ovatis acuminatis chartaceis pallide viridibus tripinnatis, pinnulis omnibus sublonge petiolulatis obcordato-cuneatis apice crenato-serratis in sinu profundo monosoris, venis flabellatis dichotome divisis, involucro suborbiculare coriaceo atro-fusco.

Hab. Hill-sides, near Simoda, Japan, C. Wright; Tsus Sima, Strait of Korea, Wilford, n. 837.

A very elegant and unquestionably a very distinct species of Adiantum, well named monochlamys by its first describer. Among my specimens there is no instance of more than one sorus on each pinnule, and that arises from a deep sinus at the almost truncated apex.

Tab. L. Fertile plant; nat. size. Fig. 1. Back view of a fertile pinnule. f. 2 Front view showing the sorus: magnified.
Asplenium (§ Anisogonium) ternatum, Liebm.

Fronde coriacea glabra ternata 5-10-poll. longa, 2½-3½ poll. lata, stipite 2-7-policari, pinna media lateralis longiorc 3-5 poll. longa 1-1½ poll. lata elliptica utrinque attenuata apice longe acuminata petiolata, petiolo 4-6 poll. longo, margine imprimis apicem versus remote et grosse dentato; pinnis lateralis oppositis inequalibus, 1-4 poll. longis 1-1½ poll. lati falcato-elliptici brevipetiolati acuminati grosse dentati; pagina anteriori obscura viridi posteriori glauco-viridi; costa media antice canaliculata, postice convexa, venis utrinque prominulis nigris pluribus furcatis bicollis in areolam ellipticam anastomosantibus; soris 3-4 lines longis simplicibus vel diplazioideis, indusiis integris membranaceis fuscis, stipite antice et lateribus sulcato, postice convexo.—Rhizoma subterraneum obliquum breve pennam anserinam crassum radiculis simplicibus validis et intricatis et fragmentis stipitum emortuorum tectum.—Liebm.

Hab. Mexico, Distr. of Oajaca elev. 4-5000 feet, Liebmann.

My specimens of this plant, from the author, will be better understood by the accompanying figures taken from them than by words. The species has the characters in part of Asplenium, of Diplazium, and Anisogonium; and to those who maintain those genera respectively, it would be difficult to say to which of the three it has the strongest claim.

TAB. LI. Plants; nat. size. Fig. 1. Portion of a pinna showing the venation and sori;—magnified. f. 2. Portion of a sorus more highly magnified.
NOTHOCHLÆNA FERRUGINEA, Hook.

Caudice repente longe fibroso bulbillis ovatis squamosis demum frondiferis onusto, stipitibus aggregatis 2–4 pollicaribus rigidiis tomentosis demum nudis aterrimis, frondibus 6–8–10–pollicaribus erectis coriaceis firmis lanceolatis pinnatis, pin-
nitalibus sessilibus subsemiunciam longis obtusis pin-
natifidis, supra villosis subtiis denissimis ferrugino-v. albo-
pannosis, laciniis utrinque 6–8 breviuseulis ovato-oblongis
uniformibus, marginibus magis minusve revolutis subinvolve-
eriformibus, soris aterrimis.

Notochlæna trichomanoides, Mart. et Gal. Fil. Mex. p. 45,
(not Br.)

HAB. Peru (Vahl, Herb. and Poeppig); Columbia (Moritz);
Guatemala, and Mexico are given as localities for this
Fern; and in the latter country it appears to be a frequent
inhabitant of the mountains, at elevations varying from 3 to
5000 feet. Jamaica, St. Andrew's Parish, near Shalloten-
burgh Great House, elev. 3–4000, on rocks and shingly
soil fully exposed, Mr. Nathaniel Wilson. If Willdenow's
Acerstichum Bonariense be the same plant, as implied by
Mettenius' synonyms, it is a native of Buenos-Ayres; but
this requires further confirmation. May not that be the
Notochlæna hypoleuca? a nearly allied species, known to
be a native of Chili.

This is a very elegant Fern, and now for the first time
found in the West Indies by Mr. Wilson, the indefatigable
superintendent of the Botanic Garden in Jamaica. Genericaly
this borders very closely upon Cheilanthes, and has nearly as
good a claim to rank with the one Genus as with the other.

Tab. LII. Fig. 1. Plant of the ferruginous state of
Notochlæna ferruginea; f. 2. The white state; natural size.
f. 3. Segment with sorî, magnified; f. 4. Portion of a fertile
segment, more highly magnified.
Caudice repente ferrugineo-tomentoso-squamuloso, stipitibus sparsis firmis flexuosis semipedalibus ad pedalem basi squamulosis, frondibus coriaceis subdeltoidoe-acuminatis sparsis 3-4-pinnatis, pinnis primariis ovato-lanceolatis valde acuminatis pinnatifidis ultimis lanceolatis dentato-pinnatifidis dentibus soriferis, soris intramarginalibus cupuliformibus.

Hab. Canalla, New Caledonia, Mr. Charles Moore, n. 5.

This species of Davallia, belonging to the group or section Eudavallia, possesses no very strikingly marked characters, and yet cannot be referred to any known species. It comes too from a country in the Australian S. Pacific Ocean, which would doubtless yield a good harvest of new Ferns, could it be fully investigated by the Botanist.

Tab. LIII. Plant of Davallia Moorei; natural size. Fig. 1. Ultimate pinna, fertile. f. 2. Single sorus;—magnified.
Davallia (§ Dareoideæ) fœniculacea, Hook.

Frondibus sesquipedalibus (et ultra?) subcoriaceo-herbaceis latè ovatis acuminatis 4-pinnatis, divisionibus primariis circumscriptiisque ovato-lancolatis tenui-acuminatis 6-8 pollicicarisibus, secundariis tertiariumque lancolatis segmentis angustissime linearibus ultimis vix lineam longis subclavatis, soris copiosis, involucris solitariis suburceolatis ad marginem interiorem infra apicem oblique sitiis.

Hab. Naviti Levu of the Fiji Islands, in woods on mountains, Milne, in the Voy. of the Herald, under Capt. Denham, R.N.

The most finely and deeply cut of all the genus Davallia. The resemblance to fennel leaves is indeed weakened by the very copious sori, which are situated on the interior margin of most of the ultimate segments, and so prominent, and so oblique in direction, that a fertile segment not inaptly resembles a tobacco-pipe, with a crest or wing on one side.

A very obscure costa passes through all the segments; indeed the ramification is of that character that it may be as correctly described 3-4-pinnatifid as pinnate.

Tab. LIV. Fig. 1. Primary branch or division of Davallia fœniculacea; natural size. f. 2. Ultimate segments, one fertile, —magnified; f. 3. Fertile segment, more magnified.
Davallia (§ Daceoideæ) Fœniculacea, Hook.

Frondibus sesquipedalibus (et ultra?) subcoriaceo-herbaceis late ovatis acuminatis 4-pinnatis, divisionibus primariis circumscriptione ovato-lancolatis tenui-acuminatis 6-8 pollicari bus, secundariis tertiarisque lancolatis segmentis angustissime linearibus ultimis vix lineam longis subclavatis, soris copiosis, involucris solitariis suburceolatis ad marginem interiorem infra apicem oblique sitis.

Hab. Naviti Levu of the Fiji Islands, in woods on mountains, Milne, in the Voy. of the Herald, under Capt. Denham, R.N.

The most finely and deeply cut of all the genus Davallia. The resemblance to fennel leaves is indeed weakened by the very copious sori, which are situated on the interior margin of most of the ultimate segments, and so prominent, and so oblique in direction, that a fertile segment not inaptly resembles a tobacco-pipe, with a crest or wing on one side. A very obscure costa passes through all the segments; indeed the ramification is of that character that it may be as correctly described 3-4-pinnatifid as pinnate.

Tab. LIV. Fig. 1. Primary branch or division of Davallia fœniculacea; natural size. f. 2. Ultimate segments, one fertile, —magnified; f. 3. Fertile segment, more magnified.
Hemionitis lanceolata, Hook.

Stipite 8-10-pollicari crasso badio nitido, fronde subæque longa coriaceo-membranacea firma lato-lanceolata acuminata anguste marginata costata, costa valida subitus prominentem fusca nitidissima, venis patentibus ubique anastomosantibus areolas oblongas hexagonas formantibus, venis omnibus soriferis.

This quite accords in generic character with the original Hemionitis of Linnaeus, and is the only known species of that genus, with quite undivided fronds. Indeed without the sori, and without observing the venation, this plant would pass for an Acrostichum of the Elaphoglossum group. Only 2 specimens of it appear to have been preserved by Milne, and these are destitute of caudex: but in other respects they are very perfect. The veins are all connected just within the margin by a longitudinal vein as represented at our fig. 2.

Tab. LV. Hemionitis lanceolata; nat. size. Fig. 1. Portion of fertile frond; magnified. f. 2. Section showing the marginal venation, magnified. f. 3. Sori more highly magnified.
Davallia (Odontoloma) La peyrousii, Hook.

Caudice brevi repente, stipitibus brevibus bipollicaribus aggregatis, frondibus 6 uncias ad sesquipedalem herbaccis lanceolatis pinnatis basi angustatis, pinnis numcrosis pollicaribus horizontalibus semiyovalis falcatis, parte inferiore integra, superiore profunde pinnatifida, laciniis 6-8 anguste cuneatis apice truncatis subsimnatus rarissime bi-trifidis, venis simplicibus v. furcatis, soris infra apicem sitis, involucris reniformi-oblongis transversis membranaceis subintegris, rachi stricta straminea nitida.

Hab. Island of Vanikolla or Pitt’s Island, S. Pacific Ocean, the site of the disastrous shipwreck of La Peyrouse in 1788, Mr. Charles Moore. Naviti Levu, Fiji Islands, damp places on mountains, Milne, in Capt. Denham’s Voyage of the Herald.

This Davallia, though quite distinct from, is nevertheless nearly allied to, the very elegant Davallia Blumeana, Hook. (Sp. Fil. p. 177, t. 54. A) from Java. That species is bipinnate; this simply pinnate. Our first specimens received were from Mr. Moore, gathered in the island which was the scene of the shipwreck of the unfortunate La Peyrouse, from which circumstance I have derived the specific name.

Tab. LVI. Davallia La Peyrousii; nat. size.—Fig. 1. Sterile segments; magnified, and f. 3 & 4, fertile segments; more magnified.
Aspidium (Polystichum) tripterum, Kze.

Caudice brevi erecto crasso squamis magnis ovatis acuminatis paleaceis, stipitibus caespitosis semipedalis ad pedalem stramineis inferne squamosis, frondibus 1-1½ pcd. submembranaceis circumscripitione hastato-lanceolatis acuminatis pinnatis, pinnis numerosis 1½ unciam longis horizontalibus sessilibus e basi oblique cunctata superne auriculata lanceolatis grosse serratibus setoso-mucronatis subts rachibusque parce albo-paleaceis, infinis duabus suboppositis 4-6-uncialibus iternum pinnatis, soris plerisque subbiserialibus, involucris parvis orbicularibus peltatis demum obsolentis.

Hab. Island of Tsus Sima, Gulf of Korea, Wilford. Japan, Goring; Hakodadi, C. P. Hodgson, Esq.

A species well distinguished among the Polystichum-group of Aspidium by the flaccid and submembranaceous texture, simply pinnate, except the lowest pair of pinnæ; these are greatly elongated and again pinnate, resembling two ears, and spreading so horizontally as to form in circumscription a hastate frond. In the more advanced state of the fructification, the delicate involucre is so shrunk and concealed by the copious capsules of the sori that the Fern resembles a Polypondium (§ Phegopteris.)

Tab. LVII. Aspidium tripterum; nat. size. Fig. 1. Portion of a pinna with young sori. f. 2. An old sorus, with the involucre nearly obsolete;—magnified.
Niphobolus linearifolius, Hook.

Caudice longe repente ramoso sæpe copioso radiculoso squamis subulatis ferrugineis dense imbricatis nitidis setoso-paleaceo, frondibus sparsis erectis carnoso-coriaceis sessilibus 3-4 uncias longis 1 lineam latis linearibus totis pilis stellatis pallide ferrugineis tectis, demum superne præcipue nudiusculis viridibus, soris oblongo-rotundatis biserialibus series in dimidiam superiorem frondis, venis remotis anastomosantisbus, areolis appendiculatis.

Hab. Island of Tsus Sima, gulf of Korea, growing on rocks along with Pleopeltis nuda, Hook. (Polypodium sesquipedale, Wall.)

The genus Niphobolus of Kaulfuss, is one among the Polypodioid Ferns that is retained by some Botanists and rejected by others. Few as are its characters, it is generally easily distinguished by its habit and its stellato-tomentose covering. Its venation is very indistinct and difficult to be seen and to be accurately represented, and is said by Presl to be different in different species. Then as to specific differences they depend mostly on the outline of the fronds which are uniformly undivided. In favor of this being considered distinct I may observe that its fronds are so narrow and so uniformly small (4 inches being the extreme length) that it is at once distinguishable from every other kind known to me.

Tab. LVIII. Plant of Niphobolus linearifolius; nat. size. Fig. 1. Apex of a fertile frond;—magnified. f. 2. Fertile portion, more highly magnified, and exhibiting the venation. f. 3. Tuft of stellated hairs; very highly magnified.
Hypolepis pteridioides, Hook.

Stipite stramineo, fronde (ut videtur) ampla, basi trichotome et pedatim divisa 3-4-pinnata submembranacea glabra sic-citate olivacea, pinnis primariis subsesquipedalibus oblique ovatis acuminatis petiolatis reliquis sessilibus lanceolatis acuminatis profunde fere ad costam pinnatifidis apieibus acuminatis serrato-lobatis, lacinis vix semipolliearibus oblongis obtuse erenato-serratis margine utrinque monosoris, venis remotis liberis infra medium furcatis ramis patentibus, sori (in depressione seu cavitate frondis) impressis, involueris transversim oblongis fuscis, rachibus stramincis nitidis, costis versum apicem pinnarum supra spinulosis.

HAB. Peak of Fernando Po, at 7000 feet elevation, Gustav Mann. n. 348.

The habit of this Fern, whose fronds are probably too large to be preserved entire, seems to be quite that of some exotic species of Pteris (Eupteris) of the group to which Pt. arguta, Ait. and Pt. flabellata, Thunb. belong, and in some of them the sori are in a degree abbreviated, but here they are as much so as (or more than) in many species of Adiantum, and which have induced me to refer this species to Hypolepis. In the present plant I never find more than one sorus on each side of a segment, and these sori are invariably sunk in a cavity or depression, which occasions a correspondent swelling, of the same form, on the superior side of the frond.

TAB. LI X. Fig. 1, 2. Portions of a fertile frond of Hypolepis pteridioides; —nat. size. f. 2, 3. Sori seen from beneath, and f. 4. Impressions caused by the sori, as seen on the superior side of the segment; more or less magnified.
Asplenium (Darea) Mannii, Hook.

Nanum, caudice filiformi sarmentoso longe repente intricato copiose radiculoso, stipitis subaggregatis vix biuncialibus gracilibus, frondibus biuncialibus oblongo-ovatis subcarnosocoriaceis viridibus bipinnatis, pinnis remotis, pinnulis subunilateralibus, sterilibus linearibus obtusis, fertilibus apice oblique semiovatis rostratis monosoritis, involucro (ratione plantae) ampio laxe membranaceo.

Hab. Peak of Fernando Po, elev. 3000 feet above the level of the sea, epiphytal, Gustav Mann.

Evidently one of the Darea-group of Asplenium, but extremely unlike any described species, though allied to A. brachypterum of Kunze: yet it can hardly be a state of that; the caudex and pinnules and habit are so different. The former resembles a slender filiform stolon, forming dense copious intricated masses, at distances throwing out tufted fibrous roots, on the undersides, and a few clustered fronds on the upper. The fertile segments with their oblique semiovate apex almost exactly resemble in shape the Buxbaumia aphyllo among mosses, and the delicate membranaceous involucre is large and lax. The term pinnatifid is more applicable to these fronds than pinnate: a single vein passes through the centre and terminates in a clavate apex below the extremity of each segment; from the upper side this sorus arises.

Tab. LX. Portion of a tuft of Asplenium Mannii, nat. size. Fig. 1. Anterior side of a fertile pinna or segment, and f. 2. Posterior, or underside of ditto;—magnified.

Cent. 2, t. 60.
**Adiantum (Euadiantum) flexuosum, Hook.**

**Hab.** Santa Rosa, Vera Paz, in hollows of pine ridges, Guatemala, Osbert Salvyn, Esq.

A new species and a very distinctly marked one, peculiar in the scandent habit, in the refracted pinnæ (as is common in other scandent ferns) and in the asperous zigzag rachis.

**Tab. LXI. Fig. 1, 2, 3. Portions of Adiantum flexuosum; nat. size. f. 4. Fertile pinnule; magnified. f. 5. Sorus, more highly magnified.**
Nephrodium (Lastrea) Milnei, Hook.

Stipite rachibusque primariis intense nigro-ebeneo nitidis, frondibus sesquipedalibus ovatis acuminitatis membranaceois atro-viridibus opacis bipinnatis, pinnis primariis ovatis petiolatis, secundariis sessilibus lanceolatis profunde pinnatifidis lobis oblongis obtusis usque usque sub-pin-natifidisve, sinibus lobulo acuto donatis, venis remotis simplicibus medium versus unisoris, involuero carnoso-celluloso cordato-reniformi, marginibus dentatis dentibus glandula globosa terminatis.

Hab. Wooded mountains, interior of Naviti Levu, Fiji Islands, Alex. Milne, Denham’s Voyage of H.M.S. Herald.

I cannot refer this to any described species of the Lastrea group of Nephrodium. It presents few striking distinguishing characters. The stipes (as much as was gathered) and the main rachises are indeed singularly black and ebeneous; and on many of the ultimate pinnae the sinuses are furnished with an acute lobe, or tooth (see our fig. 2).

Tab. LXII. Fig. 1. Portion of Nephrodium Milnei;—nat. size. f. 2. Segment of a pinna with sori;—magnified. f. 3. Sorus;—more highly magnified.
Trichomanes cellulosum, Kl.

Caudice medioëri ascendente vel longe repente rigidissime fibroso-radienuloso, stipitibus sparsis approximatis 2-4 uncialibus superne alatis firmis atris, frondibus 2-4 uneis longis rigidis atro-viridibus laxe cellulosis (areolis subrotundis) tri-4-pinnatis seu potius pinnatipendis, laeiniis eopiosis subpatentibus linearibus seu subspathulatis obtusis integerrimis, costa centrali erassa rigid, soris copiosis marginalibus laciniis brevibus terminantium, involucro brevi-cylindraceo marginato ore paululum dilatato integro, collumella elongata longe exserto erasso.

Tr. filiforme, J. W. Sturm, in Mart. l. e. p. 269, t. 18, f. 14?
(The two figures in Martius are represented in “nature-printing,” excluding the caudex, and give no idea of the fructification or of the nature of the frond.)

Hab. Tropical America; Roraima, British Guiana, Robt. Schomburgk, and Kumuku Mountains, Rich. Schomburkg, n. 1184; Valley of the Amazon; Baña of Rio Negro and San Carlos, N. Brazil, R. Spruce, n. 1399, 2278 (n. 873, according to Sturm,) and n. 2838, segments of the fronds a little broader and more opaque.

Few who have not studied the numerous individuals of the family of Hymenophyllaceae, can have an idea of the difficulty that attends their correct discrimination. Happily Dr. van den Bosch, for some time distinguished by his valuable writings on the Mosses of the Netherlands possessions in the Malay Archipelago, has taken up this beautiful group of Ferns, with an amount of knowledge and of zeal which augurs well for the Monograph, and many of the species are to be illustrated by figures. The present species seems to be peculiar to B. Guiana and to the valley of the Amazon; and judging by the references to Spruce’s specimens, T. filiforme of J. W. Sturm in Martius is only a var. of it.

Tab. LXIII. Exhibits a plant of Trichomanes cellulosum, Kl.:—nat. size. f. 1. Portion of a pinna with fructification. f. 2. Involucre laid open to show the capsules at the base of the columnar receptacle;—magnified.
DAVALLIA (CUNEA TE?) TRICHOMANOIDES, Hook.

Caudice? stipite subspithamæo (et ultra?) fusco-viridi toretæ, fronde perelegante pedali et ultra ovata acuminata 4-pinнатæ seu decomposita, pinnis primariis 4-8 uncias longis ovato-lancicolatis, secundariis 1-2 uncias longis, lacinii omnibus angustissimis linearí-spathulatís obtusis vix linearí longis plerisque soriferis, soris terminalibus, involucro oblongo-lingulato segmentis angustiore, costa lata, rachibus stramineo-viridibus nitidis.

HAB. Wooded Mountains, Naviti Levu, Fiji Islands, Alex. Milne in Voyage of H.M.S. Herald, Capt. Denham, R.N.

This is assuredly the most elegant of the genus Davallia, so narrow in its segments that they seem to be composed of the midrib with a very narrow herbaceous margin. The apices of the fertile segments which are very copious have the appearance of being unequally 2-lipped: the segment itself being much dilated, and the involucre, an oblong or tongue-shaped scale, is appressed to it, quite concealing the sorus or cluster of capsules in its axis.

TAB. LXIV. Represents a primary pinna of Davallia trichomanoides, with fructification; natural size. Fig. 1. Segments, of which one is fertile; magnified. f. 2. Apex of a segment with involucre, and f. 3, the same, with the involucre removed, showing the sorus of capsules on long pedicels: more magnified.

CENT. 2, p. 64.
Anemia Mexicana, Kl.; var. paucifolia.

Elata, frondibus pinnatis, pinnis 3-13 ovatis obtusis magis minusve acuminatis serratis brevi-petiolatis glabris pennivenis, venulis diehotomis libris, spicis pedunculatis pin- natis, pinnis pinnatifidis apice confluentibus lobis capsuli- feris oblongis longe villosis.

β. paucifolia; minor, frondibus ternatis. (Tab. Nostr. LXV.)

This plant which is maintained as a distinct species, under the not very appropriate name of A. speciosa, by Presl and Liebmann (from whom I have received authentic specimens), I can only consider as variety of Anemia Mexicana, a variety probably occasioned by its locality, at a considerable elevation on the mountains. The fronds are of a firmer texture, the pinnæ are fewer, generally 3, and these shorter and blunter.

Tab. LXV. Plants, sterile and fertile, of Anemia Mexicana, β.; natural size. Fig. 1. Portion of a sterile pinna; and f. 2, Portion of a fertile spike; magnified.

Cent. 2, t. 65.
Alsophila podophylla, Hook.

Frondibus bi-tri-(quadri?)-pinnatis glabris, pinnulis 4-6-pollicaribus petiolatis lineari-oblongo-lanceolatis coriaceo-membranaceis acuminatis sinuato-dentatis basi truncatis apice serratis terminali pinnatifido-lobato majore subtus pallidioribus, venis infimis solummodo cum proxima vena anastomosantibus, soris copiosis sparsis globosis, capsulis compactis, receptaculo magno hemisphærico, costa subtus pubescenti-squamulosa.

Hab. Chusan, Alexander. Hong Kong, Dr. Harland, J. C. Bowring, Esq. Col. Urquhart; abundant at the foot of Victoria Peak, in a ravine, Wilford.

A very distinct and well marked species; its nearest ally is probably Als. gigantea, Wall. The caudex is 4-8 feet high. Fronds 8-9 feet long. Stipes densely scaly below, and, as well as the main rachises, bright castaneous when dry, rough to the touch, but not to the naked eye, with minute raised points. Veins in fascicles; the lowest veinlet in each fascicle very frequently uniting with the lower one of the opposite fascicle and thus forming a triangular areole next the costa, the rest of the veinlets free. This plant would probably be a Gymnosphaera of Blume and may be, and possibly is, his G. glabra; but with the very brief character given by that author of less than two lines, it is impossible to form any decided opinion, one way or the other.

Tab. LXVI. Figs. 1, 2, 3. Portions of a frond of Alsophila podophylla, sterile and fertile; natural size. f. 4. Portion of a fertile pinna, showing the venation; magnified. f. 5. Single sorus, and f. 6. Receptacle, from which the capsules have fallen; more magnified.
Nephrodium (Lastrea) Fijiense, *Hook.*

Fronde ampla bipedali et ultra submembranacea firma sicci-tate fusco-viridi late ovato-acuminata bipinnata, pinnis primariis remotis ovatis acuminatis petiolatis (supremis exceptis), secundariis seu pinnulis oblongo-linearibus acutis sessilibus profunde fere ad costam pinnatifidis, segmentis oblongo-ovatis ciliatis obtusis inferioribus pinnatifido-lobatis reliquis subintegris, soris biseriatis in dorso venularum, involucris orbiculari-cordatis pilis clavatis ciliatis, stipite rachibusque ferrugineo-paleaceo-hirsutis.

Hab. Naviti Levu, Fiji Islands, *Miihe,* n. 159, on mountains, not common.

I am not aware of any described species of the *Lastrea*-group to which this can be referred. There is nothing to correspond with it among the Lastreas in Brackenridge's Ferns of the Fijian group.

Tab. LXVII. *Fig.* 1. Primary pinna with a portion of the main rachis, and *f.* 2. Apex of a frond of *Nephrodium Fijiense*;—*natural size.* *f.* 3. Fertile segment of a frond, with sori; *f.* 4. Single sorus. *f.* 5. Portion of an involucrum; all more or less *magnified.*
Asplenium (Euasplenium) Induratum, Hook.

Caudice repente radicante, stipitibus approximatis atris biuncialibus squamosis, squamis subulato-setaceis atris basi laeiniatis, frondibus 4-6 uncialibus eretis lanceolatis rigido-chartaceis olivaceo-viridibus pinnatis, pinnis subsessilibus horizontalibus 4-5 lineas longis 2½ latis semi-ovatis basi superne productis apice obtusis nunc leviter falcatis ernato-serratis, venis remotiusculis, soris obliquis biserialibus linearibus, involueris rigide coriaceis fuscis, rachiatro-villosa.

This will perhaps rank near Aspl. hirtum of the Furcatum-group of Euasplenium, of which it may possibly prove to be a small variety. All the specimens however are very uniform, and none exceeds in size those here represented. Some of them have lost their lower pinna, as if they separated at a joint, as in so many species of Nephrolepis. This may be an accidental circumstance, arising probably from a season of unusual heat and drought; so that I have not ventured to indicate it in our figure.

Tab. LXVIII. Plant of Asplenium induratum;—natural size. Fig. 1. Scale from the stipes, and f. 2. Pinna with sori;—magnified. f. 3. Sorus, more magnified.
Caudice brevi repente copioso fibroso, stipitibus spathamæcis et ultra nitidis, frondibus pedalibus ad bipedalem pergamentaceis (siccitate olivaceis) firmis, pinnis 5-9 late oblongo-lanceolatis, 6-8 uncialibus acuminatis proliferis v. cauda delapea truncato-emarginatis margine integerrimis v. sinuato-lobatis terminali sêpe longissimâ caudato-acuminata et apiece proliferâ, costa subtilis, venis remotis obliquis simplicibus v. furcatis, soris linearibus remotis margine approximatis.

Hab. Western tropical Africa, S. of the line, Dr. Curror; Prince’s Island, Barter in Baikie’s Niger Expedition, n. 1900; Fernando Po, on trees, Peak Mountain, at an elevation above the sea of 3000 feet, Gustav Mann, n. 341.

A good suite of specimens which I now possess of this Asplenium from the late Mr. Barter, and from Mr. Gustav Mann, has convinced me that I have erred in uniting Dr. Curror’s plant with the A. emarginatum of Palisot de Beauvois: and this will be better understood when I shall shortly give, in the present work, a figure and more perfect character of the true emarginatum. The two plants are certainly nearly allied: but the present may be known by the following characters. It is a larger and less delicate plant, of a very different and much firmer texture, resembling that of parchment: its colour when dry is a dirty olivaceous brown. The pinnae are entire (not serrated) and in its normal state gradually acuminate at the apex; and the terminal pinna is not, though larger than the lateral ones, materially altered in shape: but it often happens that the pinnae are proliferous, then the lateral ones are narrowly ciliate at the apex and a scaly bud forms: when this becomes a plant and falls away a deep and wide notch takes its place. If the terminal pinna is proliferous it is remarkably and gradually attenuated (to the length of 1 or 1½ foot) and the apex copiously proliferous. The sori are always distant and are situated nearer the margin than the costa: the reverse is the case in A. emarginatum.

TAB. LXIX. Represents a proliferous frond of Asplenium longicauda;—natural size. Fig. 1. Portion of a fertile pinna, with a sôr us, magnified.
TAB. LXX.

**Antrophyum Galeottii, Fée.**

Caudice vix repente subnullo, radicibus fibrosis copiosis et cespitosis dense ferrugineo-tomentosis, frondibus aggregatis spithameis ad pedalibus lorato-lanceolatis acuminaetis flaccidis sessilibus, costa latiuscula obscura, venis immersis indistinctis anastomosantibus areolis oblongis, soris linearibus submarginalibus simplicibus vel elongatis ramosis nunc anastomosantibus.

Antrophyum falcatum, *Mart. et Gal.* p. 49, t. 12 (*not Blume*).

This is probably a very rare Fern, apparently peculiar to Mexico, where it has been detected by Galeotti and Hartweg, and Guatemala, whence we have specimens from Mr. Skinner, and most beautiful ones from Mr. Salvin. Like some other *Antrophyya* it has perfectly sessile fronds, and since we have satisfied ourselves that it has anastomosing venation, and sometimes anastomosing sori, though that is by no means inconsistent with *Antrophyum,* we retain it in the Genus of which it is a true member. Mr. Moore (under his Genus *Scoliosorus*) says, "This plant having neither netted veins nor netted sori, cannot belong to *Antrophyum,* and is quite different from every other established Genus.

**TAB. LXX.** Fertile plant of *Antrophyum Galeottii,* Hook. *Fig. 1.* Portion of a fertile frond, with sori;—magnified.
Caudice repente squamoso radicibusque fusco-tomentosis, frondibus remotis subsphitamais submembranaccis herba-
ceis lanceolatis basi late attenuatis sessilibus costatis linea-
que centrali pallida, soris versus apicem biserialibus cos-
tamque approximatis erecto-patentibus linearis oblong-
gises.

Hab. Vera Paz, Guatemala, elev. 3500 to 5000 feet, Osbert Salvin, Esq.

In color, texture, and a good deal in form, this Fern has a
very considerable affinity with our Antrophyum Galeottii
(Tab. 70); but there are characters present too important
to allow the two to be considered identical, whether in respect
to species or even Genus. The form is different, exactly
lanceolate not at all approaching to lorate (strap-shaped) the
texture is much more pellucid so that the venation is readily
distinguishable (which is so indistinct in the Antrophyum as
to have escaped the notice of some authors.) We have
already, in describing the Antrophyum Galeottii, spoken of
the frequent presence of short linear or oblong soris in series,
as in Grammitis; but such are always nearer the margin than
the costa, and invariably mixed with branched, if not anas-
tomosing soris; here, on the other hand, the soris are placed
nearer the costa than the margin, with great regularity; and
though varying in length, always undivided, everything
indeed indicating the section Loxogramme of the Genus
Grammitis. This species we name in compliment to Osbert
Salvin, Esq., who allowed us to share in a beautiful collection
of Ferns he lately collected in Guatemala and Mexico.

**Tab. LXXI.** Fertile plant of Grammitis Salvinii, Hook.: natural size. *Fig.* 1. Portion of a fertile frond, with a linear
sorus. *f.* 2. Portion of fertile frond, with an oblong sorus;—

Cheilanthes intramarginalis, Hook.
Var. grosse serrata.

Var. Segmentis fertilibus grosse serratis. Metten. l. c. p. 50, f. 38-41. (Tab. Nostr. LXXXII.)

Hab. Mexico and Guatemala, Martens et Galeotti, Volcan de Agua, Guatemala, elev. 6000-7000 feet, Osbert Salvin, Esq.

In what has been considered the normal state of this plant, the sterile fronds alone exhibit, and very indistinctly, serratures; the fertile fronds none. But beautiful specimens before us of this species (some of them 18 inches long), in full fructification, have the segments so strongly serrated that I at first looked upon this as a new species, and it certainly is that state of Cheilanthes intramarginalis, which Martens and Galeotti published as distinct from that species under the name of Pteris fallax. It is a satisfaction to us to find that Mettenius in his recent work on the Genus Cheilanthes, agrees with us in referring the plant to Cheilanthes, rather than to Pteris, or Allosorus, or Pellaea, or Cassebeera, or Platyloma, in which several genera it has been placed according to the respective views of authors who have written upon it.

Tab. LXXII. Represents a fertile frond of Cheilanthes intramarginalis, var.; natural size. Fig. 1. Fertile pinna. f. 2. Portion of an involucre; and f. 3. Portion of a sterile pinna;—magnified.

Cent. 2. t. 72.
Antrophyum Mannianum, Hook.

Caudice brevi repente dense tomentoso-radieuloso, stipitibus approximatis graelibus complanatis, frondibus amplis 6-8 eineas longis latisque rhomboe-rotundatis membranaceis firmis subpellueidis (sicitate fusco-olivaeis) caudato-aen-

minatis subsinuato-serratis basi brevissime attenuatis, venis conspicuis elevatis ubique anastomosantibus, areolis oblongis, soris superficialibus sepe interruptis vel subcontinuis.

Hab. Epiphytal, on trees, Peak of Fernando Po, at an elevation of 3000 feet above the sea level, Gustav Mann, n. 367.

This is unquestionably the finest species of the beautiful Genus Antrophyum yet known to us: and is one of the many novelties that rewarded our admirable collector, Mr. Gustav Mann, for his late arduous but successful ascent of the famous tropical Peak of Fernando Po, whose elevation is estimated at 10,700 feet. The nearest affinity of the species is, doubtless, with the A. latifolium, Blume, Fl. Jav. p. 75, in note, (A. Boryanum, in the text, and on the plate, Tab. 31, and of Fée, but not of Kaulfuss, or Hook. et Grev.): but it is truly distinct; Blume’s plant being much smaller, of a carnoso-coriaceous, very firm texture, quite opaque when dry, with sunken veins; its colour, when dry, pale yellowish green, so that the copious brown sori which occupy the disk (not extending to the margin) are exceedingly conspicuous on the pale coloured frond; the base is gradually attenuated into the shorter and broader stipites.—In our plant the dry dark-colored frond is so membranaceous and pellueid that the minutely cellular texture is distinctly seen with a magnifying lens of small power, and the venation is very conspicuous, slender, firm, and as it were prominent (not sunk).

Tab. LXXIII. Plant of Antrophyum Mannianum, Hook., fertile; nat size. Fig. 1. Portion of a fertile frond, with sori; magnified.
Equisetum giganteum, L.

Cauli erecto stricto 10-14-pedali et ultra diametro unciam sequiunciam arete striato leviusculo copiose verticillatum ramoso, ramis patentissimis numerois 6-12 uncias longis gaueilibus semilinéam ad lincau lati simplicibus vel parce ramulosis asperiusculis, cauli vaginis unciam longis (sic- citeae pallide testaceis), dentibus subulatis aterrimis magis minusve unitis sepc semiunciam longis, ramorum dentibus parvis libris albis rarius atris, amentis ovato-cylindraceis acutis semilopollicarios.

Equisetum Poeppigianum; A. Braun, Mst. in Fil. Lecliler. p. 21, and in Lechl. Pl. Peruv, n. 1556, f. 2, name only.
Equisetum ramosum, altissimum, Plumier, Plant. Amer. 2, p. 115. t. 125.
Hab. West Indies, Plumier; Jamaica, Sloane; Arica, Peru, Lecliler.

We are accustomed to see in geological collections fossil specimens of gigantic European Equiseta, such as neither Europe nor any part of the old world now possess in a living state; but tropical America affords the present remarkable existing species which almost vies with the fossil forms above alluded to. Plumier has well represented a portion of the plant from Martinique. Sloane, and Patrick Brown, and Lunan record a very large “arborescent” Equisetum in Jamaica, no doubt this species. Lecliler’s specimens are very much broken, for the plant seems very fragile, and our representations are all fragmentary. Lecliler found it at Arica in Peru. No author however has made any mention of its height. Our friend, Mr. Spruce, in all probability alludes to this species when writing from the interior of South America, of a gigantic species of Equisetum, 20 feet high!

Tab. LXXIV. Fig. 1, 2, 3. Portions from different parts of a main stem of Equisetum giganteum L.; and f. 4. Fertile branch of the same; natural size. f. 5. Young spike or amentum of flowers; not yet emerged from its sheath, slightly magnified. f. 6. Fully formed spike, ditto; f. 7. Front view of a fertile scale of the amentum; f. 8. Side view of ditto; and f. 9 and 10. Capsules with their clavate, spiral filaments;—magnified.

Cest. 2. t. 74.
Asplenium (Euasplenium) Barteri, Hook.

Parvum, caudice subnullo, radicibus copiosissimis caespitosi, stipitibus aggregatis gracilibus 1-2 uncialibus nigro-brunneis, frondibus subquadriuncialibus membranaceis atroviridibus pinnatis, pinnis 30-35 semiunciam longis horizontalibus approximatis nunc omnibus oppositis sessilibus oblongis acutis basi oblique truncatis serratis superne auriculatis, terminali elongata gracili remote pinnatifida sepe prolifera, venis remotiusculis, soris oblongis, rachi intense fusca compresso-alata.

Hab. Tropical Western Africa; Aboh, on Trees, Barter, in Baikie's Niger Exped. n. 1454.

This pretty Asplenium may rank near A. pteropus, Kaulf., and Hook. Sp. Fil. p. 122, t. 177; but it is very different from that and every other of the Genus with which I am acquainted. Instead of tapering gradually to an acuminated apex, the frond is, as it were, suddenly truncated and a terminal pinna set on of a different shape from the lateral ones, and very generally proliferous.

Tab. LXXV. Asplenium Barteri, Hook; natural size. Fig. 1. Fertile pinna; magnified; and f. 2. Sori, more highly magnified.
Lygodium (Eulygodium) polystachyum, Wall.

Villosulum, longe scandens, ramis bipinnatis, pinnis remotis geminatis 1-1½ pedalis ad basin sæpe gemmiferis, pinnulis alternis remotis petiolumatis in petiolum articulatis, sterilibus fertilibus conformibus oblongis vel ovato-lanceolatis pinnatiædis, segmentis oblongis obtusis, fertilibum laciniis soriferis, rachibus pubescentibus hinc longeque ferrugineo-villosis, venis liberis.

Lygodium polystachyum, Wall. Cat. n. 2200.

Hab. Malayan Archipelago and Peninsula. Woody mountains of Pulo-Penang, Wallich, Mergui (Griffith) and Tonglow, and Mergui, Rev. C. S. P. Parish, n. 46, Moulmaine, Thos. Lobb.

An undescribed species of Lygodium, and unquestionably among the most distinct of the Genus. Dr. Wallich was the first to discover it, and we have specimens also from Griffith, and from Mr. Parish. It appears to be an extensive climber, the main rachis is deciduously villous and pubescent. The primary pinnaæ spring in pairs from one point or side of the main rachis, and often bear a shaggy gemma between them at the base. The pinnaæ are 2-2½ inches long, and what is, as far as I know, peculiar to this species, the fertile pinnae do not essentially differ from the sterile ones, they are merely a little narrower, and the segments, somewhat contracted, bear the two rows of capsules on the underside.

TAB. LXXVI.  

Fig. 1. Portion of a fertile plant, of Lygodium polystachyum, Wall.; natural size. f. 2. Sterile pinna; nat. size. f. 3. Sterile segment; magnified. f. 4. Fertile segment; magnified. f. 5. Sorus; and f. 6. Capsule; more magnified.

CUT. 2. T. 76
Caudice longe repente squamis membranaceis rigidis subulatis nigro-costatis paleaeo, stipitibus approximatis demum nudis purpureo-ebeneis, frondibus linearibus spithamensis pinnatis, pinmis alternis remotiusculis subsessilibus cordato-ovatis obtusis crasso-coriaceis lobato-pinnatis supra nudis subtus densissime albido-v.-ferrugineo-pannoso-villosis, lobis 5-9 rotundatis obtusis, marginibus submcrassatis patentibus, soris marginalibus continuis, capsulis magnis,

Much as this is allied in habit and general appearance to the South American Notochlæna rufa (see Tab. LII. of this volume) and to some other species of that Genus, and of Cheilanthes of S. America, it is in reality extremely different. The caudex is long and creeping, clothed with imbricating, subulate, erosive scales, which are very rigid in consequence of the broad black costa which runs through the centre. The pinnae are green, and free from tomentum above, beneath densely woolly, sometimes rich tawny or ferruginous, sometimes nearly white. The margin is not reflexed, nor at all involucriform, so that the black capsules are quite exposed, forming a continuous line along the margin.

This is well described by Pappe and Rawson in their Synopsis of the Ferns of S. Africa, and is very rare in the Colony, only one locality having yet been discovered, and that was detected by the Rev. Mr. Whitehead. I am indebted to Wm. Rawson, Esq. C.B., and to Rear-Admiral Sir Frederick Grey, K.C.B., for fine specimens.

Tab. LXXVII. Plant with sterile and fertile fronds of Notochlæna Rawsoni, Pappe; natural size. Fig 1. Scale from the caudex; f. 2. Upper side of a pinna; f. 3. Under side of a fertile pinna; f. 4. Portion of sorus; f. 5. Capsule; f. 6. Hairs from the tomentum at the back of the frond; all more or less magnified.
Gymnopteris (Leptochilus) minor, Hoeh.

Parva, caudice repente crassitie penne anserinae apice squamoso, stipitibus remotis gracilibus filiformibus, frondibus sterilibus membranaceis oblongis lato-lanccolatisve costatis in stipitem 2-2½ uncias longum attenuatis, venis anastomosantibus angulato-areolatis, areolis appendiculatis prope marginem minoribus, venulis ultimis clavatis liberis; frondibus fertilibus biuncialibus linearibus in stipitem quatuor uncias longum attenuatis.

Leptochilus minor, Fée, Acrost. p. 87, t. 25, f. 87 (excl. the synonym of Gymnopteris normalis, J. Sm.)

Hab. Subtropical region, Khasia, near Churra, elev. 2-3000 feet; Hook. fil. et Thomson. Isle of Samar, Philippines, Cuming, n. 326 (according to Fée).

That this is the Leptochilus minor of Fée, there can be no doubt; and that author seems to have taken his figure from Cuming's Phillipine Island plant, n. 326 (the only locality he gives for the species), and he quotes J. Smith's Gymnopteris normalis, a name, without description unfortunately, to Cuming's n. 326; but that number in my Herbarium has quite, or nearly quite, sessile sterile fronds, whereas Fée's plant he figures and describes "frondibus sterilibus longe petiolatis:" so that it would appear that two species have been distributed by Mr. Cuming under the same number. The present one is remarkable for its small size, and the great comparative length and slenderness of the stipites; especially of the fertile ones.

Tab. LXXVIII. Plants of Gymnopteris minor, Hook.; natural size. Fig. 1. Portion of a sterile frond; and f. 2. Portion of a fertile frond; magnified.
Antrophyum Brookei, Hook.

Caudice repente subulato-squamoso densissimae olivaceo-tomentoso, frondibus caespitosis membranaceis flaccidis 3-pollinaribus ad spathameam lineari-lanceolatis acuminatis basi attenuatis sessilibus ecostatis, soris angusti linearibus 2-4 sepe longe continuis simplicibus nunc interruptis et parce ramosis immersis, venis anastomossantibus areolas valde elongatas margini parallelas formantibus, capsulis pilis articulatis intermixtis.

The caudex of this is creeping, but as well as the roots, often densely covered with a mass of olivaceous tomentum, so as scarcely to be visible. Where the tufts of fronds arise the caudex is seen to be paleaceous with subulate scales. Fronds membranaceous, flaccid, three inches to a span, or almost a foot long, one-third of an inch wide in the broadest part, narrow, linear-lanceolate, acuminate, much tapering below, but not stipitate; a darkish line indeed runs through the very narrow base, but nothing that can be called a mid-rib. The sori vary in form. In one specimen two uninterrupted longitudinal lines run for a length of five inches between the centre and the margins, and a third but shorter continuous line appears between one of these and the margin; in other specimens the sori form two to four somewhat parallel lines, here and there branched and variously interrupted; all are sunk in a channel or groove in the substance of the frond, and all arise from the veins which run longitudinally, while oblique veinlets unite them so as to form very elongated areoles.

I can no where find any Fern described corresponding with this. It seems to approach the Antroph. angustatum of Brackenridge from Tahiti; but that has a stipes four inches long. It very much resembles in general aspect the Antroph. lineatum, Kaulf. (Polytaenium lineatum, Desv. and Hook. Gen. Fil. Tab. CVII.), but that has copious parallel sori and a distinct costa. Our Antrophyum Galeottii (see Tab. LXX. of this volume), has the areoles and sori oblique.

Tab. LXXIX. Fig. 1 & 3. Antrophyum Brookei, Hook.; fertile plants; natural size. f. 2. Portion of a frond, showing the venation. f. 3. Grooved receptacle of the capsules. f. 4. Capsule and accompanying articulated hairs; magnified.
Asplenium (Euasplenium) emarginatum, Beauv.

Caudice brevi crasso erecto dense fibroso-radicoso, stipitibus aggregatis rachique subherbaceis, fronde ampla pedali ad sesquipedalem submembranacea pinnata late-viridi, pinnis 4-5-pollicariosibus sesquieiiam et ultra latis brevi-petiolatis oblongis obtusis dentato-serratis basi oblique cuneatis apice profunde acute emarginatis sinu gemmifera, terminali majori longe petiolata, venis patentibus copiosis uni-bifurcatis, soris numerosis approximatis costam non ad marginem approximatis, involucris angustissimis albidis.

Hab. Tropical Western Africa, Mountains of Isle du Prince, Bight of Benin, Palisot de Beauvois; Onitoba, Barter, in Baikie's Niger Expedition, n. 1735. Fernando Po, on mountains 1000 feet of elev. Gustav Mann, n. 343.

I am led to believe, in consequence of more perfect specimens I have lately received of Beauvois' Asplenium emarginatum, that Dr. Curror's specimens alluded to in my habitats for that plant in the Species Filicum, are different from M. de Beauvois', and I gladly correct my error, by publishing at our Tab. LXIX. of this volume, Dr. Curror's plant under the name of A. longicauda, while I here represent what I believe to be quite different, and the true plant of the author of the "Flora d'Oware et de Benin". It will be at once seen that the present plant entirely wants the suddenly acuminated points to the apices of the former species, and equally the very long prolificous terminal pinna; here all the pinnae are obtuse and emarginate. The texture of the frond is more membranaceous, of a brighter green, and the veins are more compact, the sori much closer, and longer and narrower.

Tab. LXXX. Frond of Asplenium emarginatum, Beauv.: natural size. Fig. 1. Portion of a fertile pinna, with sori; magnified. f. 2. Two lateral pinnae, fertile; natural size.
Caudice ascendente radiculoso crasso, stipitibus spathaeis et ultra caespitosi rigidis atro-purpureo-ebeneis nitidis inferne subulato-squamosi, frondibus 4-pollicaribus coriaceis opacis cordiformibus profundissime tripartitis 5-lobo-palmatis, divisionibus primariorum infimis semitriangularibus intermedia triangulari omnibus bipinnatifidis lacinii ultimi oblongo-lanceolatis acutiusculis sinibus acutis, sori copiosis uniformibus, involucris subrotundis reniformibusve pallide fuscis venis furcatas terminantibus, costis subtus aterrimis nitidis.

Hab. Moramballa Mountain, Zambesi, elev. 3000-3500 feet.

Dr. Kirk, in Dr. Livingstone's Zambesi Expedition, Dec. 1858.

This very interesting plant has so entirely the habit and general structure of the well known Pteris, or Pellea as it is now by many called, geraniifolia, (see first Cent. of Ferns, Tab. 15), that, without fructification, I cannot point a single character by which the one can be distinguished from the other; but the sori of our present plant, are everywhere, and upon all our specimens, so entirely these of Cheilanthes, that, so long as that genus retains a place in our system, this plant must be referred to it. It is true we have had occasion to remark of several species of Cheilanthes, such a degree of confinence in the sori as to render it doubtful whether they should belong to one genus or the other, but here we have in the sori of Pellea geraniifolia and of Cheilanthes Kirkii the extremes of the two kinds of fructification, uniformly distinct in the one, and quite continuous in the other.

Tab. LXXXI. Plant of Cheilanthes Kirkii, Hook.; natural size. Fig. 1. Fertile segment of a frond; magnified; f. 2. Portion of a segment with sori, and showing the venation; more magnified.
TAB. LXXXH.

Asplenium (Euasplenium) Seelosii, Leyb.

Nanum, frondibus longe stipitatis trifoliolatis, foliolis sessilibus lanceolatis integerrmis vel grosse serratis undique distincte hirsutis pilis diaphanis, involucris albidis marginibus suber- osis approximatis subimbricatis.

Asplenium tridactylites, Bartl. in Herb. Kze. and Bolle in Herb. Hook. (sterile fronds, simple, three lobed).

Hab. Clefts of Dolomitic rocks, at an elevation of from 4-6000 feet, on the south and north-west side of the Schleern-geberg, in South Tyrol, Seelos, C. Bolle.

This is perhaps the rarest of all European Ferns, confined to a very limited locality in South Tyrol. The affinity is evidently with small specimens of Aspl. septentrionale or Aspl. Germanicum, and hence the plant would be an Acropteris of Link. The only specimens I possess were obligingly sent to me by Dr. Bolle; they were accompanied with the locality “près de Salurn, au pied du Mont Gcier, dans les fentes des rochers calcaires, Tyrol meridionale.”

Tab. LXXXH: Fig. 1, 2, & 6. Plants of Asplenium Seelosii, Leyb. fertile and sterile; natural size. f. 4. Perfect state of the fertile frond, upper side; f. 5. Fertile pinna, seen from beneath. f. 3. Portion of a fertile pinna, with two sori; all more or less magnified.
Selaginella Sprucei, Hook.

Semipedalis ad pedalem, caule inferne repente stolonifero superne ascendentc pinnatim ramoso, ramis seu pinnis elongatis arete foliosis obtusis 6-9 lineas latis, foliis horizontalibus lingulato-oblongis obtusis uninervis minute serrulatis basi superiore dilatato-rotundatis, stipulis triplo minoribus ovatis acuminatis subfalcatis erectis imbricatis, amentis copiosis omnino lateralis uneliam sesquium aium longis flexuosis sutetragonis saepissime deflexis, bracteis ovatis subacuminatis paululum carinatis.

Hab. On a mountain called Campana, near Tarapoto, Eastern Peru, R. Spruce, n. 4623.

This, I have reason to believe, is quite new, and certainly a most lovely species, worthy of bearing the name of so distinguished a traveller and so able a Botanist, as its discoverer, Mr. Richard Spruce. Its nearest affinity is perhaps with S. Breyu, Spring.

Tab. LXXXIII. Upper portion of a plant of Selaginella Sprucei, Hook.; nat. size. Fig. 1. Upper side of a portion of a branch, with leaves, stipules and a spike or amentum; magnified. f. 2. Leaf; more magnified. f. 3. Bractea and capsule, and f. 4. Spores; more magnified.
Selaginella subarborescens, Hook.

Caulc sesquipedali erecto terete parce ct appresse folioso basi radicoso, superne frondoso pinnatim ct dichotome ramoso; fronde coriacea erecta 12-16 uncias longa, pinnulis vel ramulis 6-8 uncialibus semiunciam latis linearibus acuminatis apice fertilibus subtus pallidoribus; foliis exacte horizontalibus oblongis acuminato-acutis paululum falcatis integerrimis uninervis, stipulis parvis erectis imbricatis, amencis terminalibus parvis bini ternisve lineari-oblongis nunc subramosis; bracteis cordato-ovatis acuminatis suberratis.

Hab. Rio Uapés, tributary of the Amazon, Brazil, in a forest near Juaraté-Cochoira, R. Spruce, n. 2540.

This noble species is, perhaps, the tallest of the genus, the largest specimens that came under Mr. Spruce’s notice, he observes, were 4½ feet high: so that I have thought the name of subarborescens not inappropriate. The leaves on the stipes are close pressed, dark green, ovate, very distant, upwards they gradually, as it were, pass into the foliage of the frondose portion. The stipules are remarkably small in proportion to the size of the leaves.

Tab. LXXXIV. Stipes and portion of a frond of Selaginella subarborescens, Hook.;—natural size. Fig. 1. Stipules and leaves, seen from above; f. 2. The same seen from beneath;—magnified. f. 3. Capsule; f. 4. One of the three seeds from the capsule; f. 5. Bractea and antheridium, and f. 4. Pollen grain; all more highly magnified.
Selaginella densifolia, Spruce.

Quadri-sexuncialis, procumbens, subcoriacea, nitidissima (subtus præcipue) bipinnatim ramosa copiose flagellifero-radi-cans, ramis lato-lincaris siccatate supra canaliculatis subtus convexis $1\frac{1}{2}-2$ lin. latis apice fructiferis, foliiis dense imbricatis patentibus oblongis obtusis inæquilateralibus uninnerviis serratis inferne ciliatis basi superiore dilatatis rotundatis, stipulis parvulis ovatis acuminatis imbricatis, amentis terminalibus solitariis vel binis semiunciam longis, bracteis imbricatis ovatis acuminatis serratis.

Selaginella densifolia, Spruce, mst. in Herb. nostr.

Hab. Cerro de Morro, in shady moist places of the River Orinoco, R. Spruce, n. 3809.

A small but extremely elegant species, remarkable for its very compact, densely imbricated and glossy foliage, dark green above, pale beneath; and for the copious flagelliform roots, which descend from the underside of the plant.

Tab. LXXXV. Plant of Selaginella densifolia, Spruce; natural size. Fig. 1. Apex of a branch with its amentum. f. 2. Stipules and leaves seen from above; and f. 3. Leaves seen from beneath; magnified. f. 4. Single leaf, and f. 5. Bractea, with antheridium;—more magnified.
Selaginella Vogelii, Spring.

Bi-tripedalis, caudice repente, stipite pedali ad sesquipedalem erecto nudiussculo ranisque primaris stramineo-fusco nitido, fronde stipitis longitundine orbiculari-ovata 3-4-pinnata, pinnis ultimis oblongo-linearibus, folis horizontaliter patentibus distichis subcoriaccis subsesquilineam longis, primaris longe distantibus ovato-acuminatis, reliquis arcte approximatis vix imbricatis lineari-oblongis acutis integer-rimis uninervibus subottle adnatis superiore rotundata-dilatata; stipulis 4-plo minoribus ovatis longe acuminatis imbricatis, amentis lineari-oblongis terminalibus subctragonis laxis, bracteis ovato-acuminatis subserie-ratis erecto-patentibus.

Selaginella Vogelii, Spring Monogr. Lycop. p. 171.

Hab. Fernando Po. Vogel, Barter, n. 1044, 1398; Mr. Mann, n. 149; Isle of Nissobe, East Coast of S. Africa, Boivin.

Linnaeus in his Species Plantarum enumerated twenty-four species of Lycopodium. The Genus was subsequently properly divided into two, Lycopodium and Selaginella, and the number was increased by Spring, about 20 years ago, to 101 species of Lycopodium, and 209 of Selaginella. They are plants of great beauty, the latter genus especially, but notoriously difficult to be clearly discriminated and characterized, and hence with some reason they have been called the "inde-terminable Lycopodiaceae." Our own Herbarium, would now add considerably to the number of species we originally contributed to Dr. Spring’s Monograph—on the other hand we fear that this able author has needlessly multiplied species. It may be some assistance to future Monographists to give accurate figures. The present is a most lovely plant and apparently common in Fernando Po, and as far as we know is only found in that island, and in one spot off the East Coast of Africa.

Tab. LXXXVI. Caudex, stipites, and portion of a primary branch of Selaginella Vogelii, Spring;—natural size. Fig. 1. Upper side of leaves and stipules: f. 2. Under side of ditto: f. 3. Portion of a fertile spike or amentum; f. 4. Bractea and capsule, and f. 5. Capsule; all magnified.
Gymnopteris (Leptochilus) pandurifolia, Hook.

Caudice repente crassitie penae anserinae copiosae squamoso subitus valde radicante, stipitibus approximatis robustis squamis fuscis squarrosis; frondium sterilium stipite semipedali, lamina subpedali membranacea siccatate atro-viridi late ovato-oblonga panduriformi acuta, basi cordata rotundata lobata pennivcnia, venis primariis flexuosis, reliquis omnibus reticulatis angulatim areolatis, arcolis venulis clavatis ramosis appendiculatis; frondium fertilium stipite pedali, lamina quadriunciali lineari-subpanduriformi.

Hab. Mount Guayrapurima, near Tarapota, Eastern Peru, R. Spruce, n. 4741.

This would fall into that group of Gymnopteris with simple fronds, which has been distinguished by some authors as a Genus under the name of Leptochilus, but for which I can detect no valid character. The present, however, is quite distinct from any described species.

Tab. LXXXVII. Fertile and barren fronds of Gymnopteris panduriformis, Hook; natural size. Fig. 1. Portion of a sterile frond, to show the venation; magnified. f. 2. Portion of the fertile frond; magnified.
TAB. LXXXVIII.

ACROSTICHUM (POECILOPTERIS) VIRENS, WALL.

Var. minus, fusetum.

Caudice crasso horizontali, stipitibus approximatis spithamaeis et ultra stramineis inferne sparse squamosis, frondibus 1-2-pedalibus pinnatis; pinnis sterilium 9 ad 20 subsessilibus oblongo-lanceolatis subduplciato-serratis coriaceo-membranaeis sapissime late-virentibus, venis primariis pinnatis secundarioris transversis areatatis angulato-flexuosis, areolis sepe appendiculatis, costularibus majoribus inappendiculatis; fertile pininis linearibus.

Var. minus; fusetum, pinnis minoribus terminali prolifera, costis venisque primariis gracilitibus minus conspicuis.

HAB. Var. minus, fusetum. India; Conean, Mr. Law. Nilghiri, on stones by the side of streams, Koondah's Corn, elev. 6000 feet, McIvor, n. 4.

Notwithstanding the valuable labours of M. Fée and his excellent writings and figures of the Acrostichaceae, no group of Ferns requires more careful study and revision than this does. Species are, assuredly, too much multiplied, I fear on very slight grounds: and the multitude of Genera only serve to puzzle and perplex the student as well as the practical Pterodologist himself. By the section or subgenus here called "Poecilopteris" we mean that of Presl: but unfortunately, Poecilopteris of Presl, adopted by Moore as a Genus, is Bolbitis of Schott, Campium of Presl, Cyrtogonium of J. Sm. Heteroneuron of Fée, Acrostichum of the older authors: and if we look to the figures of the generic characters in Mr. Moore's "Index Fil.," Plate VII. we shall find venation of two very different kinds; thus allowing a latitude of structure not tolerated in other Fern genera.

The Acrostichum now figured I quite believe may safely be referred to the Acrost. virens, Wall., but the strongly marked primary, parallel veins here give place to others which gradually merge into an irregular anastomosing as they recede from the costa; and, at the margin, is a set of elevate, free veinlets. The color and size of the pinnas are extremely variable, and I fear that several described species will have to be considered forms of A. virens of Wallich.

Tab. LXXXVIII. Fertile plant of Acrostichum (Poecilopteris) virens, Wall; natural size. Fig. 1. Portion of a sterile pinnas, showing the venation; and fig. 2, Portion of fertile ditto; magnified.
Tab. LXXXIX.

**Lomaria (Plagiogyria) euphlebia, Kze.**

Caudice crasso lignoso pedali, frondibus in stipitibus elongatis triquetris basi incrassatis 2-3-verrucosis, 1-2-pedalibus usque ad apicem pinnatis subchartaceis olivaceo-fuscis; sterilitus lato-ovatis lanceolatis, pinnis patentibus 5-6 uncialibus motiusculis elongato-lanceolatis sessilibus acuminatis subserratis basi eglandulosis, venis subdistantibus furcatis fertilibus angustioribus magis oblongis, pinnis linearibus elongatis obtusis, involucro dentato-lacerato.

Acerostichum triquetrum, Wall. Cat. n. 25, (in part).

This belongs to an interesting group of Lomaria, which the excellent Mettenius has thought worthy to constitute a distinct Genus to which he has given the name of Plagiogyria. My reasons for preserving it in Lomaria are fully given in the third volume of my Species Filicum, v. 3, p. 2. The present one was long known in our Herbaria as the Lomaria triquetra, from Nepal, of Dr. Wallich's Mst. Catalogue. At length it was figured and described as a Japan Fern by Kunze, above quoted. Drs. Hooker and Thomson met with it, but apparently of rare occurrence, in Khasia, Griffith in Assam, and now recently Mr. Wilford sent home specimens from Tsus-sima,—thus it has a very considerable geographical range.

Tab. LXXXIX Fertile plant of Lomaria (Plagiogyria) euphlebia, Kze.; natural size. Fig. 1. Portion of a sterile pinna, showing the venation; and f. 2. Portion of a fertile pinna; magnified.
TAB. XC.

Acrostichum (Elaphoglossum) dimorphum, Hk et Gr. 

Caudicle horizontal vel ascendente crassiussculo radicante 
apice inbricatim palaceo, stipitibus copiosis approximatis 
4 uncias ad spithamean longis subrobusstis per totam lon-
gitudinem sparse palaecco-squamosis, frondibus sterilibus 
3-4-ncialibus oblongo-lanceolatis costatis obtusis corinaco-
membranacceis margino lobato-pinnatifidis junioribus minute 
squamulosis, venis oblique patentibus, costis subutus deci-
duo-squamulosis, fertilibus paulo minoribus subintegerrimis 
vel sinuato-lobulatis dorso (ut videtur) toto capsuliferis. 

Acrostichum dimorphum, Hook. et Grev. Ic. Fil. Tab. 145, 
frons fertilibis inclusa, (not "exclusa," Fée). Fée, Hist. des 
Acrost. p. 40.

Elaphoglossum dimorphum, Moore.

Hab. St. Helena, on rocks and walls, Genl. Walker, Dr. 
Shuter (who also sent specimens from Madras, but they 
were probably taken out thither from St. Helena); top of 
Diana's Peak, very common, Dr. Hooker.

This and the subject of our following plate, Acrost. (Ela-
phoglossum) bifurcatum are very remarkable plants; peculi-
to the island of St. Helena; and, as Dr. Hooker assures 
us, growing apart from each other; and, where he has seen 
them, exhibiting no appearance of being forms of one and 
the same species. Nevertheless, M. Fée, who does not admit, 
in his Histoire des Acrostichées, the A. furcatum, observes 
at p. 40. under Acrostichum dimorphum, Hook., "cette espèce 
est parfaitement tranchée, et la dissimitude des feuilles ne 
permettra pas de la méconnaître." He goes on to say "l'A bi-
furcatum pourrait bien n'être aut' autre chose qu'une forme tres-
divisée de l'A. dimorphum." Presl, having in the interim 
established his genus Microstaphyla, with no character except 
form, that I can see, to distinguish it from Elaphoglossum (his 
Olfersia); ("soruss," he says "acrostichoideus"), founded on a 
solitary species, the Acrost. bifurcatum, Sw., M. Fée in his 
7me "Mém. sur les Fougères," adopts the Genus, repeats his 
views respecting the oneness of Acr. dimorphum and Acr. 
bifurcatum, and asserts that our figure of the former "pêche 
par l'exactitude, la fronde fertile figurée n'appartenant pas 
vaisssemblablement aux frondes steriles." He describes and 
represents the sori of Microstaphyla as "nervillaires," which 
we cannot confirm by our specimens. We must refer our 
readers to the next following description for further obser-
vations on these two Ferns.

TAB. XC. Fertile and sterile fronds of Acrostichum (Ela-
phoglossum) dimorphum, Hook. and Grev.; natural size. 
Fig. 1. Portion of a sterile, and f. 2. portion of a fertile 
frond; magnified.
TAB. XCI.

**Acrostichum (Elaphoglossum) bifurcatum, Sw.**

Glaberrimum nudum, caudice horizontali vel ascendente crassuscelo radicate apice solummodo squamoso, stipitibus dense cespitosis gracilibus 3-6-uncialibus straminco-fuscis, frondibus 2-4-uncialibus oblongo-lanceolatis pinnatis, rachibus alatis; pinnis sterilibus elongatis linearioblongis remotis simplicibus pleisque furcatis vel bifurcatis costatis seu uninervis, *frigicia* pinnis approximatis brevioribus euncatis vel subquadratris apice bi-teris vel bi-trifurcatis.

Anogramme paradoxa, *Fée, Gen. Fil.* p. 64.

Gymnogramme bifurcata, *Kze in Linn. N. F.* 10, p. 496.

Polybotrya bifurcata, *Moore.*

Hab. St. Helena, and judging from the quantity of specimens we have received from different voyagers, it must be infinitely more abundant than the subject of our last plate, *Acr. dimorphum*; on wet rocks and mossy banks, to an altitude of 1000 feet and more above the level of the sea (Hook. fil.). Plukent records it and figures it more than 100 years ago as "Filicula corniculata Insulae Sanctae Helenae," &c. My Herbarium contains specimens from the late Sir G. Strange, collected on the voyage of Lord Macartney's Embassy to China, from Menzies, Dr. Shuter, Cuming, n. 420 and 421, Nuttall, Lady Dalhousie, Dr. Lyall, Seaman, J. D. Hooker, and it is only the latter and Dr. Shuter who appear to have gathered the *A. dimorphum*; also Förster, Lichtenstein, and Liebold are recorded as having gathered this species.

I have already stated under *Acrost. dimorphum* (see our last plate XC,) that M. Fée pronounces that and the present plant to be one and the same, without even making a variety. "Nous avons sous les yeux divers modifications qui semblent établir le passage de l'une à l'autre par des nuances insensibles." My own copious specimens I must confess lead me to an opposite conclusion, and I have represented in our figures its extreme forms. *A. bifurcatum* has much longer and slenderer stipites, always destitute of scales, as is every part of the plant. It is true that in the fertile fronds there is a great tendency to become entire, less deeply divided than in the sterile fronds (as is still more strikingly seen in an allied group of *Acrostichum, Rhipidopteris*, Schott), but it goes no further than our figures show. If *A. dimorphum* were to break up into *A. bifurcatum*, the venation must undergo a considerable change; for whereas in *A. dimorphum* the veins are simple or only once forked, here they are not uncommonly twice forked, the segments having the same ramification; hence the specific name.

TAB. XCI. Sterile and fertile fronds of *Acrostichum (Elaphoglossum) bifurcatum*, Sw., *natural size*. Fig. 1. Pinna of a sterile frond, and f. 2 and 3, Pinna of fertile fronds; *magnified.*

*Gen. 2.* t. 91.
Acrostichum (Elaphoglossum) Féei, Bory.

Caudice longe repente et, ut videtur, arboribus scandente radicoso squamis ovato-acuminatis paleacis, stipitis sparsis paleaceis; frondibus sterilibus sesquiangularibus oblongo-lanceolatis obtusis grosse subcrenato-lobatis parce squamulosis in petiolum äquatlongum basi attenuatis costatis pinnatifidus venosis, venis remotis infra medium furcatis ante marginem terminantibus apicibus clavatis; fertilibus subduplo minoribus elliptico-oblongis integerrimis petiolo duplo triplo brevioribus.

Acrostichum Féei, Bory, in Fée, Acrostich. p. 48, tab. 18, f. 2. Elaphoglossum Féei, Moore.

This is justly considered, by M. Fée, who has first described and figured this pretty Acrostichum, to have the habit of Polypodium serpens, Sw.

Tab. XCII. Plant of Acrostichum (Elaphoglossum) Féei, Bory; natural size. Fig. 1. Sterile frond; f. 2. Portion of a sterile frond, and f. 3, portion of a fertile frond; all more or less magnified.
Davallia (Dareoide,e) nigrescens, Hook.

Stipite pedali et ultra subrobusto viridi-fusco squamis subulatis parvis paleaceo, fronde sesquipedali ad bipedalem latc ovata acuminata submembranacea flaeida glaberrima sicci- tate nigrescente 3-4-pinnata, pinnis primariis secundariis-que ovato-lanceolatis longe acuminatis petiolatis ultimis pinnatifidis, laciniis oblongis ovatis subsecundis acutis integerrimis uninerviis, nervis infra apicem terminantibus, soris ad marginem superiorem pinnularum seu laciniarum insertis prominentibus, involucro calyciformi (hemisphérico) firma frondis colore margine integerrimo, rachibus ubique planiusculis leviter marginato-alatis.

Hab. Peak of Fernando Po; elev. 3000 feet. Gustav. Mann, n, 448.

It is difficult to say whether this should be referred to Davallia or to Dicksonia. If considered a Davallia, the portion of the frond to which the involucre is attached, is so tumid as to represent, on the upper side of the frond, the invo- lucre on the underside, thus exhibiting a perfectly hemispher- ical cup with an entire margin, but sunk in the frond. In habit and ramification it very much resembles Asplenium (Daren) Shuttleworthii of Kunze in Schh. Fil. Suppl. p. 26, t. 14; but there the sorus and involucre are truly dareoid, laterally elongated; here hemispherical.

Tab. XCIII. Fig. 1. Portion of stipes of Davallia nigres- cens, Hook.; and f. 2 and 3, apex and primary pinna of a frond; natural size. f. 4. Ultimate fertile pinna with sorus; magnified. f. 5. Sorus from which the involucre is removed, showing the long stipitate capsules; more magnified.
Helminthostachys Zeylanica, Hook.

Helminthostachys Zeylanica.

Ophioglossum laciniatum, Rumph. Herb. Amb. 6, p. 153, t. 68, f. 3.

Botryopteris Mexicana, Presl, Rel. Hank. 1, p. 76, t. 12, f. 1.

Hymenostachys crenata, Presl, Suppl. Tent. Pterid. p. 60.

Hab. Malayan and Molucca islands, frequent; Amboyna, Rumph; Luzon, Cuming, n. 39; Tavoy and Bengal, Wallich; Mergui, Griffith; Java, Blume, Thos. Lobb; Borneo, Thos. Lobb; Ceylon, Gardner; Cochin, Mrs. General Walker, Johnston; New Caledonia, La Billardiere; Guahan, Mari-anne Islands, Hwane.

Of this remarkable Genus there is but a solitary species known: notwithstanding that Presl makes three species out of that distributed by Cuming from Luzon. One of these is the same as the Botryopteris Mexicana of the same author in the "Reliquiae Haenheanae"—afterwards, on finding that it was not a Mexican plant, and a Hymenostachys, the name was changed to H. crenata. The figure is a very good representation of the true H. Zeylanica, save the reticulated venation, which is no doubt occasioned by the ingenuity of the artist.

Tab. XCIV. Fertile plant of Helminthostachys Zeylanica, Hook.; natural size. Fig. 1. Portion of a sterile frond, showing the venation. f. 2. Portion of a fertile spike, with elustres of capsules; and f. 3. single cluster of capsules with its crest; all more or less magnified.

Cent. 2. t. 91.
TAB. XCV.

MARATTIA (EUPODIUM) KAULFUSSI, J. Sm.

Fronde “vasta” tri-quadripinnata, pinnulis ultimis oblongis ovalibusve pinnatifidis obtusi acutisve pinnatis, venis simplicibus vel furcatis, rachibus junioribus late interrupte alatis, soris in quoque lobo solitariis v. binis, involucro pedicellato.

Marattia lævis, Kaulf. Enum. Fil. p. 31 (excl. syn. omn.)

Marattia alata, Raddi, Fil. Bras. t. 83-84, (excl. syn. omn.)

Hab. Tropical S. America: Brasil, about Rio, Raddi, Beyrich, Dr. Lyall, J. D. Hooker, Martius, Vautier, Riedel and others. Antioquia, Jervise; Columbia, Triana, Purdie; Venezuela, Fenilier, n. 3 ; Caraccas, Linden, n. 196.

I fear both the genera and species of the Marattiaceous Ferns have been needlessly multiplied. The present one, however, is well distinguished from both Marattia lævis and M. alata, with which it had been confounded, and as clearly shown by Mr. J. Smith, by the presence of a distinct pedicel to the sorus. There is a further character in the uniformly pinnatifid ultimate pinna; but the entire genus requires to be carefully elaborated. I cannot agree with those who consider this a distinct Genus, on account of the pedicellated fruit.

TAB. XCV. Fig 1. Inferior portion of a fertile or primary pinna; and f. 2. apex of the same, of Marattia (Eupodium) Kaulfussii, J. Sm. natural size. f. 3. Ultimate sterile pinna and portion of the rachis, and f. 4. portion of a fertile pinna, with sori; magnified. f. 5. Sorus, with its pedicel, more magnified.

Cent. 2. t. 95.
Laxe molliter villosa, caudice repente apice paleaceo, stipitibus gracilibus sparsi patenti-villosis 4-5 uneias longis, frondibus membranaceis oblongis acuminatis, junioribus pinnatis, pinnis oblongis obtusi serrato-lobatis, adultis subspithamæis pinnatis, pinnis petiolatis ovato-lanceolatis acuminatis profundè pinnatifidis, laeiniis oblongo-lanceolatis aeutis serrato-pinnatifidis, soris in dentibus vel lobulis laeiniarum cuneato-rohdundatis longe villosis, venis pinnatis.

HAB. Tsus Sima, island off the coast of Corea, Wilford, n. 793.

A very delicate Davallia, which I refer to the Leucostegia-group, and which may rank near to Davallia membranacea, Wall.; differing in the more contracted frond, the differently shaped sori, which are here quite marginal on short teeth or lobes, but especially in the copious long, soft, white, jointed hairs of the entire frond.

TAB. CXVI. Plant with fertile and sterile frond of Davallia pilosella, Hook.; natural size. Fig. 1. Segment of a frond with two sori; magnified. f. 2. single sorus, more magnified; and f. 3. single sorus, with the involucre removed, showing the capsules, ditto.
Polybotrya Lechleriana, Metten.

Caudice crasso elongato seandente squamis ovatis acuminatis-simis fuseis paleneo, stipitis fuseis nitidis approximatis spithameis 2-3 lineis latis inferior squamosis; fronde sterilis ampla 3-pedali et ultra submembranacea firma ubiquique (rachibusque squamulosis testaceis) villosa late ovata acuminata tripinnata, pinnis primarils subsessilibus spithameis ad pedalem remotis ovatis acuminatis, secundaris approximatis numerosis, pinnulis linearis longis equis ovo-oblongis profunde pinnafis segmentis oblongis acutiusculis vix subfalcatis univenis, venis apice elavatis; fertili pinnulis linearibus obtusissimis lobato-pinnatifidis subtilis utrinque fere ad marginem soriferis.

HAB. Shady places, St. Gavan, Peru, Lechler; Mount Guayrapurime, near Tarapota, eastern Peru, sterile frond only, sent by Mr. Spruce, 1856. Ecuador, sent by Dr. Jameson, exact locality not stated.

This is the finest and most copiously divided of any of the Acrostichaceous group of Ferns. Fragments only were known to its describer, Dr. Mettenius: but a magnificent frond has come into my possession along with Lechler’s own collection of Ferns of Peru and Chili. The only other specimens known to me are a fine barren frond with caudex, gathered at Tarapota by Mr. Spruce, and the lower half of a fertile frond sent from Ecuador by Professor Jameson. The form of the sterile pinna and segments a good deal resembles some Darea among Asplenium, or our Davallia nigrescens, represented at our plate XCIII. It will rank near Polybotrya apifolia.

Tab. XCVII. Caudex and base of a sterile frond, and primary pinna of a fertile frond of Polybotrya Lechleriiana. Metten.; natural size. Fig. 1. Pinnule of a sterile frond; f. 2. Fertile pinna seen from above, and f. 3. fertile pinna seen from beneath; magnified. f. 4. Transverse section of a fertile segment; more magnified.

Cent. 2. 2. 97.
Woodsia (Physematium) Manchuriensis, Hook.

Glaberrima, eaudice perbrevi fibroso ferungineo-squamoso, stipitibus easpitosis 1-3-uncialibus gracilibus raehibusque albo-stramineis nitidis, frondibus spithamæcis tenui-membranaceis oblongo-lanceolatis aequinatis pinnatis, pinnis sessilibus uneiam et ultra longis remotiusulis oblongis obtusis pinnatifidis, lobis oblique patentibus ovatis lato-oblongis integris vel sinuato-sublobatis unisoris, venis in singulo lobo pinnatis, venulis apice elavatis venula infima superiore ante apicem soriferam, involucro (ratione plantæ) majusculo tenui-membranaceo globoso demum apice irreguläriter rupto.

This new species of the Physematium-group of Woodsia, quite distinct from any hitherto described, was detected by Mr. Wilford, in a country whose Botany is deserving of a careful investigation, Manchuria. The involucres are of so delicate a texture that the pressure given in drying destroys their spherical form, and in that state they present the appearance of a thin membrane, but soaking in warm water restores them to their proper shape.

Tab. XCVIII. Plant with fertile fronds of Woodsia (Physematium) Manchuriensis, Hook.; natural size. Fig. 1. Fertile pinna with sori; magnified. f. 2. Segment of a fertile lobe showing the venation and sori; f. 3. the same with the sori (f. 4.) removed from the lowest superior vein; and f. 5. Old involucre, burst open; more highly magnified.
Cyathea microphylla, Metten.

Caudice 4-pedali (Lechl.) frondibus 2-3-pedalibus stipitatis (stipitibus rachibusque deciduc ferrugineo-tomentosis) oblongo-ovatis acuminatis eoriaceo-membranaceis tripinnatis sicitate fusco-olivaceis, pinnis primariis sessilibus horizontalibus remotiusculis oblongis acuminatis, secundariis approximatis oblongis obtusis, pinnulis ovato-oblongis profunde pinnatifidis, lobis oblongis subcuneatisve obtusissimis integerrimis univenis, venis ante apicem evanidis, soris copiosis dorso venarum basin versus globosis membranaceis ferrugineis nitidis deum apice irregulater fissis et in lacinis 3-4 ruptis, receptaculo elevato, capsulis helicogyratis, rachibus ultimis squamis paucis convexis flexuosis ferrugineis deciduis subtus paleaceis.

Hab. Tatanara, eastern side of the Cordilera of Peru, Lechler, in Herb. Nostr. n. 2160.

A very remarkable Cyathaceous plant, the most distinct perhaps of all the group. The underside of the fertile frond has quite a ferrugineous cast, from the hairs of the tomentum of that color, and from the copious capsules, which soon, from their original spherical form, break into a number of pieces or scales, and in a measure conceal the real shape of the small pinnules.

Tab. XCIX. Fig. 1. Base of a sterile frond; and f. 2. Underside of a primary pinna of a fertile frond of Cyathea microphylla. Metten. natural size. f. 3. Fertile pinnule with two sori, magnified. and f. 4. fully formed sorus, and f. 5. old sorus; more magnified.
Hemitelia (Amphicosmia) platylepis, Hook.

Stipite elongato castaneo nitido versus basin crassitie digitis humani, squamis maximis ovatis nitidissimis acuminatis atro-fuscis margine pallidioribus suberosis basi squamulosis paleaceis, frontibus amplissimis subcoriaceis ubique hirsutulis tripinnatis, pinnis primariis inferioribus longe petiolatis pedalis sesquipedalis ovato-oblongis, secundariis sessilibus oblongo-lanceolatis acuminatis, pinnulis 3-4 lineas longis linearibus acutis marginibus recurvatis serratis, venis furcatis ad furcaturam unisoris, racbibus adpressis villosis ultimo alatis, involucro exacte hemisphario membranaceo maro-ine ereoso-denticulato, receptaculo elevato, capsulis pilis articulatis intermixtis.

Hab. Near San Carlos, Rio Negro, tributary of the Amazon, Brazil, R. Spruce, n. 3027.

This is a Hemitelia, according to our views of the Genus, but would be an Amphicosmia of the late Mr. Gardner, Lond. Journ. of Bot. 1, p. 441; differing from Hemitelia in its free venation. The involucere is exactly the same as in our H. Hostmanni and H. Parkerii, described in the "Species Filicium," and figured in the 7th volume of our "Icones Plantarum." It is probably nearly allied to Cyathaea multiflora of Sir J. E. Smith, which has the "rachis winged," and which Gardner refers to Amphicosmia: but I have never seen an authentic specimen, which I believe only exists in the Banksian Herbarium, and which is stated to be a native of Jamaica. In general the specimens we receive of these gigantic Ferns are too imperfect for accurate description, even the stipes is often neglected, which not unfrequently affords good characters in the peculiarities of its clothing especially, as is remarkably the case in the species now under consideration; and, the involucere being very fragile, is too frequently injured, and leads one astray in regard to the Genus.

Tab. C. Fig. 1. Base of the stipes of Hemitelia (Amphicosmia) platylepis, Hook., with its remarkable large scales and the squamules at their point of insertion; and f. 2. portions of a primary pinna of a fertile frond; natural size. f. 3. Under side of a barren pinna, with a portion of the winged rachis; magnified. f. 5. Portion of a fertile pinnule, with a scrus; f. 6. Involucre and receptacle from which most of the capsules have fallen; and f. 7. capsules with accompanying hairs; more magnified.
A SECOND CENTURY OF FERNS;

BEING

FIGURES WITH BRIEF DESCRIPTIONS

OF

One Hundred

NEW, OR RARE, OR IMPERFECTLY KNOWN SPECIES OF

FERNS;

FROM VARIOUS PARTS OF THE WORLD;

BY

SIR WILLIAM JACKSON HOOKER, K.H.,

DIRECTOR OF THE ROYAL BOTANICAL GARDENS, KEW.

Patson, Jane M. Gleanings among the British Ferns; illustrated by preserved Specimens of the Ferns themselves. Handsomely bound, cloth, 10s. 6d. —— London, 1856.

Plutenet, L. Phytographia, etc. Several of the volumes which contain (among others) many excellent Figures of Ferns. 7s. per volume. Small folio and 4to. —— London, 1691, etc.

Plumier, C. Déscriptions des Plantes de l'Amerique. Folio. £1 10s. 6d. —— Paris, 1693.

"The first 50 of these fine Plates are Ferns.

Although this copy is somewhat stained in places, yet it possesses considerable interest, from the fact of its having formerly belonged to Sir Hans Sloane's Library. There is also a mass of Manuscript notes, very neatly written, apparently in the handwriting of its former possessor.

Presl, C. B. Pteridographia Tentamen, &c. 12 plates, sewed, 9s. 6d., or half-calf, lettered, 15s. —— 1836.

Sadler, J. De Filicibus Hungaricis, Transylvanis, Croatiae, &c. Sewed 3s. 6d. —— Buda, 1830.

Salisbury, R. A. On the Germination of Lycopodium denticulatum. 1s. 6d. 4to. plate —— From Linn. Trans.

Schott, H. Genera Filicum. Plates, 4to. —— Vienna, 1834, &c.

Smith, J. Enumeration of the Filices of the Isthmus of Panama. Royal 4to. 3s. —— 1858.

Sprengel, K. Introduction to Cryptogamous Plants, 2s. 6d. or cold. 5s. —— London, 1807.

Spring, A. Monographie de la Famille des Lycopodiacées. 4to. 1856, etc.

Suminski. Leszeczy-Suminski zur Entwickelungs-Geschichte der Pflanzen-Raumen (Ferns). 4to. Fine plates, 7s. 6d. —— Berlin, 1848.

Suminski. Another copy of the same, on fine paper, with the plates coloured. 12s. —— Berlin, 1848.

Swartz. Another handsomely bound copy, interleaved 16s. —— Killie, 1806.

"From the library of the late Mr. Robert Brown.

Weber und Mohr. Kryptogamische Gewächse, Filices, &c. 24mo. Cold plates, 6s. 6d. Same with plain plates, 4s. 6d. —— Kiel, 1807.

Young, E. The Ferns of Wales; illustrated by carefully-preserved specimens of Thirty-four Species. Large 4to. Handsomely bound, cloth, gilt, £1 1s. —— Neath, 1856.

A Collection of Plates of Ferns, some coloured, consisting of fifty species folio, quarto, and octavo, no duplicates, price one guinea.

William Pamplin, 46, Frieth Street, Soho, London.
